

HCL AppScan Report

Report Type: Security Report

Scan Name: DAST 2026-08-20 <https://aaca.ntua.edu.tw/Server>

Technology: DAST

Report created at: Friday, August 21, 2026

This report was generated by HCL AppScan v2.1

Summary of security issues

Critical severity issues:	1
High severity issues:	2
Medium severity issues:	6
Low severity issues:	39
Informational severity issues:	114
Total security issues:	162

Scan Information

Scan started: Thursday, August 20, 2026 7:30:07 AM (UTC)
Test policy: Default
Test Optimization: Fast

Hosts

Host: aaca.ntua.edu.tw
Port: 443
Operating system: Unknown
Web server: Unknown
Application Server: Any

Login Settings

Summary

- Issues

Issue Types

- Blind SQL Injection
- Integer Overflow
- ADNS Blind SSRF on Sensitive Headers
- Cross-Site Request Forgery
- Login Error Messages Credential Enumeration
- Missing or insecure Cross-Origin-Embedder-Policy (COEP) header
- Missing or insecure Cross-Origin-Opener-Policy (COOP) header
- Missing or insecure Cross-Origin-Resource-Policy (CORP) header
- Missing "Content-Security-Policy" header
- Missing or insecure "frame-ancestors" directive in CSP
- Permanent Cookie Contains Sensitive Session Information
- Trusted types in scripts not enforced in CSP
- Application Error
- Client-Side (JavaScript) Cookie References
- Email Address Pattern Found
- Missing "Referrer policy" Security Header
- Unsanitized user input reflected in JSON

How to Fix

- ADNS Blind SSRF on Sensitive Headers
- Application Error
- Blind SQL Injection
- Client-Side (JavaScript) Cookie References
- Cross-Site Request Forgery
- Email Address Pattern Found
- Integer Overflow
- Login Error Messages Credential Enumeration
- Missing "Content-Security-Policy" header
- Missing "Referrer policy" Security Header
- Missing or insecure "frame-ancestors" directive in CSP
- Missing or insecure Cross-Origin-Embedder-Policy (COEP) header
- Missing or insecure Cross-Origin-Opener-Policy (COOP) header
- Missing or insecure Cross-Origin-Resource-Policy (CORP) header
- Permanent Cookie Contains Sensitive Session Information

H

DAST: Integer Overflow 2

How to Fix: [Integer Overflow](#)

Issue ID:	00ae433e-f36b-1410-89cd-00f37f576f24
Severity:	High
Status	Open
Location	https://aaca.ntua.edu.tw/service/spechomepageapi/update
Domain	aaca.ntua.edu.tw
Element	->"Data"->"Section3SubTitle" (Parameter)
Path	/service/spechomepageapi/update
Scheme	https
Domain	aaca.ntua.edu.tw
CVSS	8.6
Date Created	Thursday, August 20, 2026
Last Updated	Thursday, August 20, 2026
CWE:	190

Issue 1 of 2 - Details

Difference: Parameter ->"Data"->"Section3SubTitle" manipulated from: 2 to: 4294967297

Reasoning: The application has responded with an error message, indicating an undefined state that may expose sensitive information.

Path	/server
Scheme	https
Domain	aaca.ntua.edu.tw
CVSS	6.0
Date Created	Thursday, August 20, 2026
Last Updated	Thursday, August 20, 2026
CWE:	918

Issue 1 of 1 - Details

Difference: Header Host manipulated from: aaca.ntua.edu.tw to:

v3-ping-5736-6991af1d-2a90-40d4-b763-8b4c6112f58e.adns.appsechcl.com

Reasoning: The AppScan external DNS server received a DNS query containing the Variant ID of this test, and therefore concluded the application is vulnerable.

Test Requests and Responses:

```
GET /Server HTTP/1.1

Status	Open
Location	https://aaca.ntua.edu.tw/service/gallery/querylist
Domain	aaca.ntua.edu.tw
Element	->"Condition" (Parameter)
Path	/service/gallery/querylist
Scheme	https
Domain	aaca.ntua.edu.tw
CVSS	6.5
Date Created	Thursday, August 20, 2026
Last Updated	Thursday, August 20, 2026
CWE:	352

Difference: **Parameter** `->"Condition"` manipulated from: `Progid = \"Announcement\" And _TagDetail.Lang = \"zh-tw\"` to: `1Progid = \"Announcement\" And _TagDetail.Lang = \"zh-tw\" 1`

Reasoning: The test result seems to indicate a vulnerability because the Test Response is identical to the Original Response, indicating that the Cross-Site Request Forgery attempt was successful, even though it included a manipulated CSRF-token.

```

How to Fix: [Login Error Messages Credential Enumeration](#)

Issue 1 of 1

Issue ID:	1fac433e-f36b-1410-89cd-00f37f576f24
Severity:	Medium
Status	Open
Location	https://aaca.ntua.edu.tw/service/auth/login
Domain	aaca.ntua.edu.tw
Element	Login (Page)
Path	/service/auth/login
Scheme	https
Domain	aaca.ntua.edu.tw
CVSS	6.5
Date Created	Thursday, August 20, 2026
Last Updated	Thursday, August 20, 2026
CWE:	204

Issue 1 of 1 - Details

Difference: Parameter ->"account" manipulated from: admin02 to: aadmin02WithSomeChars

Parameter ->"password" manipulated from: **CONFIDENTIAL 1* to: a**CONFIDENTIAL 1**WithSomeChars

Reasoning: The test discovered that the application issues one error message when the username field is invalid, and a different error message when the password field is invalid. This behavior may enable attackers to use a brute force technique to enumerate valid usernames and passwords.

Test Requests and Responses:

```

I DAST: Application Error 104

How to Fix: [Application Error](#)

Issue 1 of 104

Issue ID:	7aaf433e-f36b-1410-89cd-00f37f576f24
Severity:	Informational
Status	Open
Location	https://aaca.ntua.edu.tw/service/banner/querylist
Domain	aaca.ntua.edu.tw
Element	->"Fields"[0] (Parameter)
Path	/service/banner/querylist
Scheme	https
Domain	aaca.ntua.edu.tw
CVSS	0.0
Date Created	Thursday, August 20, 2026
Last Updated	Thursday, August 20, 2026
CWE:	550

Issue 1 of 104 - Details

Difference: Parameter ->"Fields"[0] manipulated from: ->"Fields"[0] to: ORIG_VAL []

Reasoning: The application has responded with an error message, indicating an undefined state that may expose sensitive information.

Test Requests and Responses:

```

Issue 16 of 104 - Audit Trail

08/20/2026 10:58:53

Issue type: ApplicationError
Location: <https://aaca.ntua.edu.tw/service/spechomepageapi/update>
Severity: Informational
CVSS: 0.0
Scanner: AppScan Dynamic Analyzer

Issue 17 of 104

Issue ID:	bcbl433e-f36b-1410-89cd-00f37f576f24
Severity:	Informational
Status	Open
Location	https://aaca.ntua.edu.tw/service/account/gettotalcounts
Domain	aaca.ntua.edu.tw
Element	->"Fields"[1] (Parameter)
Path	/service/account/gettotalcounts
Scheme	https
Domain	aaca.ntua.edu.tw
CVSS	0.0
Date Created	Thursday, August 20, 2026
Last Updated	Thursday, August 20, 2026
CWE:	550

Issue 17 of 104 - Details

Difference: Parameter `->"Fields"[1]` manipulated from: `->"Fields"[1]` to: **ORIG VAL** .

Reasoning: The application has responded with an error message, indicating an undefined state that may expose sensitive information.

Test Requests and Responses:

Issue 44 of 104

Issue ID:	f2b1433e-f36b-1410-89cd-00f37f576f24
Severity:	Informational
Status	Open
Location	https://aaca.ntua.edu.tw/service/account/querylist
Domain	aaca.ntua.edu.tw
Element	->"Condition" (Parameter)
Path	/service/account/querylist
Scheme	https
Domain	aaca.ntua.edu.tw
CVSS	0.0
Date Created	Thursday, August 20, 2026
Last Updated	Thursday, August 20, 2026
CWE:	550

Issue 44 of 104 - Details

Difference: **Parameter** `->"Condition"` manipulated from: `Progid = \"Announcement\" And _TagDetail.Lang = \"zh-tw` to: `\\`

Reasoning: The application has responded with an error message, indicating an undefined state that may expose sensitive information.

Test Requests and Responses:

Issue 101 of 104 - Audit Trail

08/20/2026 10:58:53

Issue type: `ApplicationError`

Location:

https://aaca.ntua.edu.tw/service/filemanagement/public_preview/9951f5a2-8f10-419c-93d6-4ec87afd6f08

Severity: Informational

CVSS: 0.0

Scanner: AppScan Dynamic Analyzer

Issue 102 of 104

Issue ID:	0caf433e-f36b-1410-89cd-00f37f576f24
Severity:	Informational
Status	Open
Location	https://aaca.ntua.edu.tw/service/spechomepageapi/update
Domain	aaca.ntua.edu.tw
Element	->"Data"->"_SpecHomePage1821_Shortcut"[0]->"ActionType" (Parameter)
Path	/service/spechomepageapi/update
Scheme	https
Domain	aaca.ntua.edu.tw
CVSS	0.0
Date Created	Thursday, August 20, 2026
Last Updated	Thursday, August 20, 2026
CWE:	550

Issue 102 of 104 - Details

Difference: Parameter ->"Data"->"_SpecHomePage1821_Shortcut"[0]->"ActionType" manipulated from: — to: %00

Reasoning: The application has responded with an error message, indicating an undefined state that may expose sensitive information.

Last Updated	Thursday, August 20, 2026
CWE:	79

Issue 2 of 4 - Details

Difference: Parameter ->"Data"->"Card2Title" manipulated from: 大學招生專業化發展計畫專區 to: http%3A%2F%2F0x000A.0x0000F4.0x0000.0x00000C2%3A42259%2FAppScanMsg.html%3FvarId%3D2718

Reasoning: The test result seems to indicate a vulnerability because the Global Validation feature found an embedded script in the response, which was probably injected by a previous test.

Test Requests and Responses:

Issue 4 of 4 - Details

Difference:	Parameter ->"Data"->"Card1Link" manipulated from: /admission-regulations/Ourschool to: /admission-regulations/Ourschool<%00script>alert(2717)</script>
Reasoning:	The test result seems to indicate a vulnerability because the Global Validation feature found an embedded script in the response, which was probably injected by a previous test.
Test Requests and Responses:

How to Fix

M ADNS Blind SSRF on Sensitive Headers

Cause

Incorrect processing, sanitation, or validation of user input that contain elements later joined with URI

Risk

It is possible to manipulate the server into processing, sending, or retrieving information in an unintended, insecure manner

The application sends requests to resources using externally-influenced input, and fails to neutralize elements that could be used to abuse internal or external functionality.

This can be used to cause the server to initiate unintended requests on behalf of the attacker.

There are three main examples of abuse of this vulnerability:

[1] An attacker could cause the server to leak important information, by sending information normally accessible only by the application to an external server.

[2] An attacker could cause the server to retrieve information from an untrusted source and process, store, or present it to the user.

[3] In an environment where services communicated internally, an attacker could cause an action to be performed by the server, using the server's privileges.

Example:

The application includes a common 3rd Party service that exposes REST APIs to manage users profiles.

...

```
$userPostData = http_build_query($formFields); # data will go into POST request $options
```

...

```
file_get_contents($fetchUserBioAPI, false , stream_context_create($options)); # this calls the API denoted by $service to perform an action
```

...

Example of an exploitation of this issue:

[Original HTML Form]

...

```
<FORM METHOD=GET ACTION="/userData">
```

```
<INPUT TYPE=HIDDEN NAME="fetchUserBioAPI" VALUE="https://companydomain.com/user/profile/bio">
```

...

```
</FORM>
```

[Manipulated HTML Form]

...

```
<FORM METHOD=GET ACTION="/userData">
```

```
<INPUT TYPE=HIDDEN NAME="fetchUserBioAPI" VALUE="https://localhost/activeSessions">
```

...

</FORM>

The original intent of the form was to show the user biography by calling "fetchUserBioAPI" service. By manipulating the request to call "https://localhost/activeSessions" the server will retrieve the active sessions of all the users who are logged in, an action which should have been reserved only to an administrator.

Since the call is coming from the application server and not directly to the user management service, the request is honored.

Sample Exploit: Atlassian Confluence SSRF / Remote Code Execution

[object Object]

Owasp Server Side Request Forgery:

[object Object]

Fix recommendation

There are several mitigation techniques:

[1] If possible, use library calls rather building the requests yourself.

[2] Strategy: Whitelist

Create a whitelist of servers and services that are permitted, preferably per role or function.

[3] Strategy: Libraries or Frameworks

Use a vetted library or framework that prevents this weakness occurring, or at least provides constructs that make it easier to avoid.

For example, consider using the ESAPI Encoding control

<https://owasp.org/www-project-enterprise-security-api>

or a similar tool, library, or framework. These can help to encode output.

[4] Strategy: Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications or transform it into something that does. Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if you are expecting colors such as "red" or "blue."

When constructing OS command strings, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping.

Note that proper output encoding, escaping, and quoting is the most effective solution for preventing OS command injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent OS command injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, when invoking a mail program, you might need to allow the subject field to contain otherwise-dangerous inputs like ";" and ">" characters, which would need to be escaped or otherwise handled. In this case, stripping the character might reduce the risk of OS command injection, but it would produce incorrect behavior because the subject field would not be recorded as the user intended. This might seem to be a minor inconvenience, but it could be more important when the program relies on well-structured subject lines in order to pass messages to other components.

Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not address.

[5] Strategy: Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks

<https://buildsecurityin.us-cert.gov/daisy/bsi/articles/knowledge/principles/351.html>

If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

CWE

918

Cause

Proper bounds checking were not performed on incoming parameter values
No validation was done in order to make sure that user input matches the data type expected

Risk

It is possible to gather sensitive debugging information

If an attacker probes the application by forging a request that contains parameters or parameter values other than the ones expected by the application (examples are listed below), the application may enter an undefined state that makes it vulnerable to attack. The attacker can gain useful information from the application's response to this request, which information may be exploited to locate application weaknesses.

For example, if the parameter field should be an apostrophe-quoted string (e.g. in an ASP script or SQL query), the injected apostrophe symbol will prematurely terminate the string stream, thus changing the normal flow/syntax of the script.

Another cause of vital information being revealed in error messages, is when the scripting engine, web server, or database are misconfigured.

Here are some different variants:

- [1] Remove parameter
- [2] Remove parameter value
- [3] Set parameter value to null
- [4] Set parameter value to a numeric overflow (+/- 999999999)
- [5] Set parameter value to hazardous characters, such as ' " \' \ ") ;
- [6] Append some string to a numeric parameter value
- [7] Append "." (dot) or "[]" (angle brackets) to the parameter name

Fix recommendation

[1] Check incoming requests for the presence of all expected parameters and values. When a parameter is missing, issue a proper error message or use default values.

[2] The application should verify that its input consists of valid characters (after decoding). For example, an input value containing the null byte (encoded as %00), apostrophe, quotes, etc. should be rejected.

[3] Enforce values in their expected ranges and types. If your application expects a certain parameter to have a value from a certain set, then the application should ensure that the value it receives indeed belongs to the set. For example, if your application expects a value in the range 10..99, then it should make sure that the value is indeed numeric, and that its value is in 10..99.

[4] Verify that the data belongs to the set offered to the client.

[5] Do not output debugging error messages and exceptions in a production environment.

In order to disable debugging in ASP.NET, edit your web.config file to contain the following:

```
<compilation  
debug="false"  
/>
```

For more information, see "HOW TO: Disable Debugging for ASP.NET Applications" in:

<http://support.microsoft.com/default.aspx?scid=kb;en-us;815157>
■ <http://support.microsoft.com/default.aspx?scid=kb;en-us;815157>
external

You can add input validation to Web Forms pages by using validation controls. Validation controls provide an easy-to-use mechanism for all common types of standard validation (for example, testing for valid dates or values within a range), plus ways to provide custom-written validation. In addition, validation controls allow you to completely customize how error information is displayed to the user. Validation controls can be used with any controls that are processed in a Web Forms page's class file, including both HTML and Web server controls.

To make sure that all the required parameters exist in a request, use the "RequiredFieldValidator" validation control. This control ensures that the user does not skip an entry in the web form.

To make sure user input contains only valid values, you can use one of the following validation controls:

[1] "RangeValidator": checks that a user's entry (value) is between specified lower and upper boundaries. You can check ranges within pairs of numbers, alphabetic characters, and dates.

[2] "RegularExpressionValidator": checks that the entry matches a pattern defined by a regular expression. This type of validation allows you to check for predictable sequences of characters, such as those in social security numbers, e-mail addresses, telephone numbers, postal codes, and so on.

Important note: validation controls do not block user input or change the flow of page processing; they only set an error state, and produce error messages. It is the programmer's responsibility to test the state of the controls in the code before performing further application-specific actions.

There are two ways to check for user input validity:

1. Test for a general error state:

In your code, test the page's IsValid property. This property rolls up the values of the IsValid properties of all the validation controls on the page (using a logical AND). If one of the validation controls is set to invalid, the page's property will return false.

2. Test for the error state of individual controls:

Loop through the page's Validators collection, which contains references to all the validation controls. You can then examine the IsValid property of each validation control.

**** Input Data Validation:**

While data validations may be provided as a user convenience on the client-tier, data validation must be performed on the server-tier using Servlets. Client-side validations are inherently insecure because they can be easily bypassed, e.g. by disabling Javascript.

A good design usually requires the web application framework to provide server-side utility routines to validate the following:

[1] Required field

[2] Field data type (all HTTP request parameters are Strings by default)

[3] Field length

[4] Field range

[5] Field options

[6] Field pattern

[7] Cookie values

[8] HTTP Response

A good practice is to implement the above routine as static methods in a "Validator" utility class. The following sections describe an example validator class.

[1] Required field

Always check that the field is not null and its length is greater than zero, excluding leading and trailing white spaces.

Example of how to validate required fields:

```
// Java example to validate required fields public Class Validator { ... public static boolean validateRequired(String value)
{ boolean isValid = false; if (value != null && value.trim().length() > 0) { isValid = true; } return isValid; }
... } ... String fieldValue = request.getParameter("fieldName"); if (Validator.validateRequired(fieldValue)) { // fieldValue is
valid, continue processing request ... }
```

[2] Field data type

In web applications, input parameters are poorly typed. For example, all HTTP request parameters or cookie values are of type String. The developer is responsible for verifying the input is of the correct data type. Use the Java primitive wrapper classes to check if the field value can be safely converted to the desired primitive data type.

Example of how to validate a numeric field (type int):

```
// Java example to validate that a field is an int number public Class Validator { ... public static boolean validateInt(String
value) { boolean isValid = false; try { Integer.parseInt(value); isValid = true; } catch (Exception e) { isValid
= false; } return isValid; } ... } ... // check if the HTTP request parameter is of type int String fieldValue =
request.getParameter("fieldName"); if (Validator.validateInt(fieldValue)) { // fieldValue is valid, continue processing
request ... }
```

A good practice is to convert all HTTP request parameters to their respective data types. For example, store the "integerValue" of a request parameter in a request attribute and use it as shown in the following example:

```
// Example to convert the HTTP request parameter to a primitive wrapper data type // and store this value in a request
attribute for further processing String fieldValue = request.getParameter("fieldName"); if
(Validator.validateInt(fieldValue)) { // convert fieldValue to an Integer Integer integerValue =
Integer.getInteger(fieldValue); // store integerValue in a request attribute request.setAttribute("fieldName",
integerValue); } ... // Use the request attribute for further processing Integer integerValue =
(Integer)request.getAttribute("fieldName"); ...
```

The primary Java data types that the application should handle:

- Byte
- Short
- Integer
- Long
- Float
- Double
- Date

[3] Field length

Always ensure that the input parameter (whether HTTP request parameter or cookie value) is bounded by a minimum length and/or a maximum length.

Example to validate that the length of the userName field is between 8 and 20 characters:

```
// Example to validate the field length public Class Validator { ... public static boolean validateLength(String value, int
minLength, int maxLength) { String validatedValue = value; if (!validateRequired(value)) { validatedValue = ""; } return
(validatedValue.length() >= minLength && validatedValue.length() <= maxLength); } ... } ... String userName =
request.getParameter("userName"); if (Validator.validateRequired(userName)) { if (Validator.validateLength(userName,
8, 20)) { // userName is valid, continue further processing ... } }
```

[4] Field range

Always ensure that the input parameter is within a range as defined by the functional requirements.

Example to validate that the input numberOfChoices is between 10 and 20:

```
// Example to validate the field range public Class Validator { ... public static boolean validateRange(int value, int min, int
max) { return (value >= min && value <= max); } ... } ... String fieldValue = request.getParameter("numberOfChoices");
if (Validator.validateRequired(fieldValue)) { if (Validator.validateInt(fieldValue)) { int numberOfChoices =
Integer.parseInt(fieldValue); if (Validator.validateRange(numberOfChoices, 10, 20)) { // numberOfChoices is valid,
continue processing request ... } } }
```

[5] Field options

Often, the web application presents the user with a set of options to choose from, e.g. using the SELECT HTML tag, but fails to perform server-side validation to ensure that the selected value is one of the allowed options. Remember that a malicious user can easily modify any option value. Always validate the selected user value against the allowed options as defined by the functional requirements.

Example to validate the user selection against a list of allowed options:

```
// Example to validate user selection against a list of options public Class Validator { ... public static boolean
validateOption(Object[] options, Object value) { boolean isValidValue = false; try { List list = Arrays.asList(options); if (list
!= null) { isValidValue = list.contains(value); } } catch (Exception e) { } return isValidValue; } ... } ... // Allowed options
String[] options = {"option1", "option2", "option3"}; // Verify that the user selection is one of the allowed options String
userSelection = request.getParameter("userSelection"); if (Validator.validateOption(options, userSelection)) { // valid
user selection, continue processing request ... }
```

[6] Field pattern

Always check that the user input matches a pattern as defined by the functionality requirements. For example, if the userName field should only allow alpha-numeric characters, case insensitive, then use the following regular expression:

```
^[a-zA-Z0-9]*$
```

Java 1.3 or earlier versions do not include any regular expression packages. Apache Regular Expression Package (see Resources below) is recommended for use with Java 1.3 to resolve this lack of support.

Example to perform regular expression validation:

```
// Example to validate that a given value matches a specified pattern // using the Apache regular expression package
import org.apache.regexp.RE; import org.apache.regexp.RESyntaxException; public Class Validator { ... public static
boolean matchPattern(String value, String expression) { boolean match = false; if (validateRequired(expression)) { RE r
= new RE(expression); match = r.match(value); } return match; } ... } ... // Verify that the userName request parameter
is alpha-numeric String userName = request.getParameter("userName"); if (Validator.matchPattern(userName, "^[a-zA-
Z0-9]*$")) { // userName is valid, continue processing request ... }
```

Java 1.4 introduced a new regular expression package (java.util.regex). Here is a modified version of Validator.matchPattern using the new Java 1.4 regular expression package:

```
// Example to validate that a given value matches a specified pattern // using the Java 1.4 regular expression package
import java.util.regex.Pattern; import java.util.regex.Matcher; public Class Validator { ... public static boolean
matchPattern(String value, String expression) { boolean match = false; if (validateRequired(expression)) { match =
Pattern.matches(expression, value); } return match; } ... }
```

[7] Cookie value

Use the javax.servlet.http.Cookie object to validate the cookie value. The same validation rules (described above) apply to cookie values depending on the application requirements, e.g. validate a required value, validate length, etc.

Example to validate a required cookie value:

```
// Example to validate a required cookie value // First retrieve all available cookies submitted in the HTTP request Cookie[]
```

```
cookies = request.getCookies(); if (cookies != null) { // find the "user" cookie for (int i=0; i<cookies.length; ++i) { if (cookies[i].getName().equals("user")) { // validate the cookie value if (Validator.validateRequired(cookies[i].getValue())) { // valid cookie value, continue processing request ... } } }
```

[8] HTTP Response

[8-1] Filter user input

To guard the application against cross-site scripting, sanitize HTML by converting sensitive characters to their corresponding character entities. These are the HTML sensitive characters:

```
< > " ' % ; ) ( & +
```

Example to filter a specified string by converting sensitive characters to their corresponding character entities:

```
// Example to filter sensitive data to prevent cross-site scripting public Class Validator { ... public static String filter(String value) { if (value == null) { return null; } StringBuffer result = new StringBuffer(value.length()); for (int i=0; i<value.length(); ++i) { switch (value.charAt(i)) { case '<': result.append("<"); break; case '>': result.append(">"); break; case '"': result.append("""); break; case ''': result.append("'"); break; case '%': result.append("%"); break; case ';': result.append(";"); break; case '(': result.append("("); break; case ')': result.append(")"); break; case '&': result.append("&"); break; case '+': result.append("+"); break; default: result.append(value.charAt(i)); break; } return result; } ... } ... // Filter the HTTP response using Validator.filter PrintWriter out = response.getWriter(); // set output response out.write(Validator.filter(response)); out.close();
```

The Java Servlet API 2.3 introduced Filters, which supports the interception and transformation of HTTP requests or responses.

Example of using a Servlet Filter to sanitize the response using Validator.filter:

```
// Example to filter all sensitive characters in the HTTP response using a Java Filter. // This example is for illustration purposes since it will filter all content in the response, including HTML tags! public class SensitiveCharsFilter implements Filter { ... public void doFilter(ServletRequest request, ServletResponse response, FilterChain chain) throws IOException, ServletException { PrintWriter out = response.getWriter(); ResponseWrapper wrapper = new ResponseWrapper((HttpServletResponse)response); chain.doFilter(request, wrapper); CharArrayWriter caw = new CharArrayWriter(); caw.write(Validator.filter(wrapper.toString())); response.setContentType("text/html"); response.setContentLength(caw.toString().length()); out.write(caw.toString()); out.close(); } ... public class CharResponseWrapper extends HttpServletResponseWrapper { private CharArrayWriter output; public String toString() { return output.toString(); } public CharResponseWrapper(HttpServletResponse response){ super(response); output = new CharArrayWriter(); } public PrintWriter getWriter(){ return new PrintWriter(output); } } }
```

[8-2] Secure the cookie

When storing sensitive data in a cookie, make sure to set the secure flag of the cookie in the HTTP response, using Cookie.setSecure(boolean flag) to instruct the browser to send the cookie using a secure protocol, such as HTTPS or SSL.

Example to secure the "user" cookie:

```
// Example to secure a cookie, i.e. instruct the browser to // send the cookie using a secure protocol Cookie cookie = new Cookie("user", "sensitive"); cookie.setSecure(true); response.addCookie(cookie);
```

RECOMMENDED JAVA TOOLS

The two main Java frameworks for server-side validation are:

[1] Jakarta Commons Validator (integrated with Struts 1.1)

The Jakarta Commons Validator is a powerful framework that implements all the above data validation requirements. These rules are configured in an XML file that defines input validation rules for form fields. Struts supports output filtering of dangerous characters in the [8] HTTP Response by default on all data written using the Struts 'bean:write' tag. This filtering may be disabled by setting the 'filter=false' flag.

Struts defines the following basic input validators, but custom validators may also be defined:

required: succeeds if the field contains any characters other than white space.

mask: succeeds if the value matches the regular expression given by the mask attribute.

range: succeeds if the value is within the values given by the min and max attributes ((value >= min) & (value <= max)).

maxLength: succeeds if the field is length is less than or equal to the max attribute.

minLength: succeeds if the field is length is greater than or equal to the min attribute.

byte, short, integer, long, float, double: succeeds if the value can be converted to the corresponding primitive.

date: succeeds if the value represents a valid date. A date pattern may be provided.

creditCard: succeeds if the value could be a valid credit card number.

e-mail: succeeds if the value could be a valid e-mail address.

Example to validate the userName field of a loginForm using Struts Validator:

```
<form-validation> <global> ... <validator name="required" classname="org.apache.struts.validator.FieldChecks" method="validateRequired" msg="errors.required"> </validator> <validator name="mask" classname="org.apache.struts.validator.FieldChecks" method="validateMask" msg="errors.invalid"> </validator> ... </global> <formset> <form name="loginForm"> <!-- userName is required and is alpha-numeric case insensitive --> <field property="userName" depends="required,mask"> <!-- message resource key to display if validation fails --> <msg name="mask" key="login.userName.maskmsg"/> <arg0 key="login.userName.displayName"/> <var> <var-
```

name>mask</var-name> <var-value>^[a-zA-Z0-9]*\$</var-value> </var> </field> ... </form> ... </formset> </form-validation>

[2] JavaServer Faces Technology

JavaServer Faces Technology is a set of Java APIs (JSR 127) to represent UI components, manage their state, handle events and input validation.

The JavaServer Faces API implements the following basic validators, but custom validators may be defined:

validate_doublerange: registers a DoubleRangeValidator on a component

validate_length: registers a LengthValidator on a component

validate_longrange: registers a LongRangeValidator on a component

validate_required: registers a RequiredValidator on a component

validate_stringrange: registers a StringRangeValidator on a component

validator: registers a custom Validator on a component

The JavaServer Faces API defines the following UIInput and UIOutput Renderers (Tags):

input_date: accepts a java.util.Date formatted with a java.text.Date instance

output_date: displays a java.util.Date formatted with a java.text.Date instance

input_datetime: accepts a java.util.Date formatted with a java.text.DateTime instance

output_datetime: displays a java.util.Date formatted with a java.text.DateTime instance

input_number: displays a numeric data type (java.lang.Number or primitive), formatted with a java.text.NumberFormat

output_number: displays a numeric data type (java.lang.Number or primitive), formatted with a java.text.NumberFormat

input_text: accepts a text string of one line.

output_text: displays a text string of one line.

input_time: accepts a java.util.Date, formatted with a java.text.DateFormat time instance

output_time: displays a java.util.Date, formatted with a java.text.DateFormat time instance

input_hidden: allows a page author to include a hidden variable in a page

input_secret: accepts one line of text with no spaces and displays it as a set of asterisks as it is typed

input_textarea: accepts multiple lines of text

output_errors: displays error messages for an entire page or error messages associated with a specified client identifier

output_label: displays a nested component as a label for a specified input field

output_message: displays a localized message

Example to validate the userName field of a loginForm using JavaServer Faces:

```
<%@ taglib uri="https://docs.oracle.com/javaee/6/tutorial/doc/glxce.html" prefix="h" %> <%@ taglib
uri="http://mrbool.com/how-to-create-a-login-validation-with-jsf-java-server-faces/27046" prefix="f" %> ... <jsp:useBean
id="UserBean" class="myApplication.UserBean" scope="session" /> <f:use_faces> <h:form formName="loginForm" >
<h:input_text id="userName" size="20" modelReference="UserBean.userName"> <f:validate_required/>
<f:validate_length minimum="8" maximum="20"/> </h:input_text> <!-- display errors if present --> <h:output_errors
id="loginErrors" clientId="userName"/> <h:command_button id="submit" label="Submit" commandName="submit" />
<p> </h:form> </f:use_faces>
```

**** Error Handling:**

Many J2EE web application architectures follow the Model View Controller (MVC) pattern. In this pattern a Servlet acts as a Controller. A Servlet delegates the application processing to a JavaBean such as an EJB Session Bean (the Model). The Servlet then forwards the request to a JSP (View) to render the processing results. Servlets should check all input, output, return codes, error codes and known exceptions to ensure that the expected processing actually occurred.

While data validation protects applications against malicious data tampering, a sound error handling strategy is necessary to prevent the application from inadvertently disclosing internal error messages such as exception stack traces. A good error handling strategy addresses the following items:

[1] Defining Errors

[2] Reporting Errors

[3] Rendering Errors

[4] Error Mapping

[1] Defining Errors

Hard-coded error messages in the application layer (e.g. Servlets) should be avoided. Instead, the application should use error keys that map to known application failures. A good practice is to define error keys that map to validation rules for HTML form fields or other bean properties. For example, if the "user_name" field is required, is alphanumeric, and must be unique in the database, then the following error keys should be defined:

(a) ERROR_USERNAME_REQUIRED: this error key is used to display a message notifying the user that the "user_name" field is required;

(b) ERROR_USERNAME_ALPHANUMERIC: this error key is used to display a message notifying the user that the "user_name" field should be alphanumeric;

(c) ERROR_USERNAME_DUPLICATE: this error key is used to display a message notifying the user that the "user_name" value is a duplicate in the database;

(d) ERROR_USERNAME_INVALID: this error key is used to display a generic message notifying the user that the "user_name" value is invalid;

A good practice is to define the following framework Java classes which are used to store and report application errors:

- ErrorKeys: defines all error keys

```
// Example: ErrorKeys defining the following error keys: // - ERROR_USERNAME_REQUIRED // -  
ERROR_USERNAME_ALPHANUMERIC // - ERROR_USERNAME_DUPLICATE // - ERROR_USERNAME_INVALID // ... public Class  
ErrorKeys { public static final String ERROR_USERNAME_REQUIRED = "error.username.required"; public static final String  
ERROR_USERNAME_ALPHANUMERIC = "error.username.alphanumeric"; public static final String  
ERROR_USERNAME_DUPLICATE = "error.username.duplicate"; public static final String ERROR_USERNAME_INVALID =  
"error.username.invalid"; ... }
```

- Error: encapsulates an individual error

```
// Example: Error encapsulates an error key. // Error is serializable to support code executing in multiple JVMs. public  
Class Error implements Serializable { // Constructor given a specified error key public Error(String key) { this(key, null); }  
// Constructor given a specified error key and array of placeholder objects public Error(String key, Object[] values) {  
this.key = key; this.values = values; } // Returns the error key public String getKey() { return this.key; } // Returns the  
placeholder values public Object[] getValues() { return this.values; } private String key = null; private Object[] values =  
null; }
```

- Errors: encapsulates a Collection of errors

```
// Example: Errors encapsulates the Error objects being reported to the presentation layer. // Errors are stored in a  
HashMap where the key is the bean property name and value is an // ArrayList of Error objects. public Class Errors  
implements Serializable { // Adds an Error object to the Collection of errors for the specified bean property. public void  
addError(String property, Error error) { ArrayList propertyErrors = (ArrayList)errors.get(property); if (propertyErrors ==  
null) { propertyErrors = new ArrayList(); errors.put(property, propertyErrors); } propertyErrors.put(error); } // Returns  
true if there are any errors public boolean hasErrors() { return (errors.size > 0); } // Returns the Errors for the specified  
property public ArrayList getErrors(String property) { return (ArrayList)errors.get(property); } private HashMap errors =  
new HashMap(); }
```

Using the above framework classes, here is an example to process validation errors of the "user_name" field:

```
// Example to process validation errors of the "user_name" field. Errors errors = new Errors(); String userName =  
request.getParameter("user_name"); // (a) Required validation rule if (!Validator.validateRequired(userName)) {  
errors.addError("user_name", new Error(ErrorKeys.ERROR_USERNAME_REQUIRED)); } // (b) Alpha-numeric validation rule  
else if (!Validator.matchPattern(userName, "^[a-zA-Z0-9]*$")) { errors.addError("user_name", new  
Error(ErrorKeys.ERROR_USERNAME_ALPHANUMERIC)); } else { // (c) Duplicate check validation rule // We assume that
```

```
there is an existing UserValidationEJB session bean that implements // a checkIfDuplicate() method to verify if the user
already exists in the database. try { ... if (UserValidationEJB.checkIfDuplicate(userName)) { errors.addError("user_name",
new Error(ErrorKeys.ERROR_USERNAME_DUPLICATE)); } } catch (RemoteException e) { // log the error
logger.error("Could not validate user for specified userName: " + userName); errors.addError("user_name", new
Error(ErrorKeys.ERROR_USERNAME_DUPLICATE)); } } // set the errors object in a request attribute called "errors"
request.setAttribute("errors", errors); ...
```

[2] Reporting Errors

There are two ways to report web-tier application errors:

(a) Servlet Error Mechanism

(b) JSP Error Mechanism

[2-a] Servlet Error Mechanism

A Servlet may report errors by:

- forwarding to the input JSP (having already stored the errors in a request attribute), OR
- calling response.sendError with an HTTP error code argument, OR
- throwing an exception

It is good practice to process all known application errors (as described in section [1]), store them in a request attribute, and forward to the input JSP. The input JSP should display the error messages and prompt the user to re-enter the data. The following example illustrates how to forward to an input JSP (userInput.jsp):

```
// Example to forward to the userInput.jsp following user validation errors RequestDispatcher rd =
getServletContext().getRequestDispatcher("/user/userInput.jsp"); if (rd != null) { rd.forward(request, response); }
```

If the Servlet cannot forward to a known JSP page, the second option is to report an error using the response.sendError method with HttpServletResponse.SC_INTERNAL_SERVER_ERROR (status code 500) as argument. Refer to the javadoc of javax.servlet.http.HttpServletResponse for more details on the various HTTP status codes.

Example to return a HTTP error:

```
// Example to return a HTTP error code RequestDispatcher rd =
getServletContext().getRequestDispatcher("/user/userInput.jsp"); if (rd == null) { // messages is a resource bundle with
all message keys and values response.sendError(HttpServletResponse.SC_INTERNAL_SERVER_ERROR,
messages.getMessage(ErrorKeys.ERROR_USERNAME_INVALID)); }
```

As a last resort, Servlets can throw an exception, which must be a subclass of one of the following classes:

- RuntimeException
- ServletException
- IOException

[2-b] JSP Error Mechanism

JSP pages provide a mechanism to handle runtime exceptions by defining an errorPage directive as shown in the following example:

```
<%@ page errorPage="/errors/userValidation.jsp" %>
```

Uncaught JSP exceptions are forwarded to the specified errorPage, and the original exception is set in a request parameter called javax.servlet.jsp.jspException. The error page must include a isErrorPage directive as shown below:

```
<%@ page isErrorPage="true" %>
```

The isErrorPage directive causes the "exception" variable to be initialized to the exception object being thrown.

[3] Rendering Errors

The J2SE Internationalization APIs provide utility classes for externalizing application resources and formatting messages including:

(a) Resource Bundles

(b) Message Formatting

[3-a] Resource Bundles

Resource bundles support internationalization by separating localized data from the source code that uses it. Each resource bundle stores a map of key/value pairs for a specific locale.

It is common to use or extend java.util.PropertyResourceBundle, which stores the content in an external properties file as shown in the following example:

```
##### # ErrorMessages.properties
##### # required user name error message
error.username.required=User name field is required # invalid user name format error.username.alphanumeric=User
name must be alphanumeric # duplicate user name error message error.username.duplicate=User name {0} already
exists, please choose another one ...
```

Multiple resources can be defined to support different locales (hence the name resource bundle). For example, ErrorMessages_fr.properties can be defined to support the French member of the bundle family. If the resource member

of the requested locale does not exist, the default member is used. In the above example, the default resource is `ErrorMessages.properties`. Depending on the user's locale, the application (JSP or Servlet) retrieves content from the appropriate resource.

[3-b] Message Formatting

The J2SE standard class `java.util.MessageFormat` provides a generic way to create messages with replacement placeholders. A `MessageFormat` object contains a pattern string with embedded format specifiers as shown below:

```
// Example to show how to format a message using placeholder parameters
String pattern = "User name {0} already exists, please choose another one";
String userName = request.getParameter("user_name");
Object[] args = new Object[1];
args[0] = userName;
String message = MessageFormat.format(pattern, args);
```

Here is a more comprehensive example to render error messages using `ResourceBundle` and `MessageFormat`:

```
// Example to render an error message from a localized ErrorMessages resource (properties file)
// Utility class to retrieve locale-specific error messages
public class ErrorMessageResource {
    // Returns the error message for the specified error key in the environment locale
    public String getErrorMessage(String errorKey) {
        return getErrorMessage(errorKey, defaultLocale);
    }
    // Returns the error message for the specified error key in the specified locale
    public String getErrorMessage(String errorKey, Locale locale) {
        return getErrorMessage(errorKey, null, locale);
    }
    // Returns a formatted error message for the specified error key in the specified locale
    public String getErrorMessage(String errorKey, Object[] args, Locale locale) {
        // Get localized ErrorMessageResource
        ResourceBundle errorMessageResource = ResourceBundle.getBundle("ErrorMessages", locale);
        // Get localized error message
        String errorMessage = errorMessageResource.getString(errorKey);
        if (args != null) {
            // Format the message using the specified placeholders
            return MessageFormat.format(errorMessage, args);
        } else {
            return errorMessage;
        }
    }
    // default environment locale
    private Locale defaultLocale = Locale.getDefaultLocale();
    // ... // Get the user's locale
    Locale userLocale = request.getLocale();
    // Check if there were any validation errors
    Errors errors = (Errors)request.getAttribute("errors");
    if (errors != null && errors.hasErrors()) {
        // Iterate through errors and output error messages corresponding to the "user_name" property
        ArrayList userNameErrors = errors.getErrors("user_name");
        ListIterator iterator = userNameErrors.iterator();
        while (iterator.hasNext()) {
            // Get the next error object
            Error error = (Error)iterator.next();
            String errorMessage = ErrorMessageResource.getErrorMessage(error.getKey(), userLocale);
            output.write(errorMessage + "\r\n");
        }
    }
}
```

It is recommended to define a custom JSP tag, e.g. `displayErrors`, to iterate through and render error messages as shown in the above example.

[4] Error Mapping

Normally, the Servlet Container will return a default error page corresponding to either the response status code or the exception. A mapping between the status code or the exception and a web resource may be specified using custom error pages. It is a good practice to develop static error pages that do not disclose internal error states (by default, most Servlet containers will report internal error messages). This mapping is configured in the Web Deployment Descriptor (`web.xml`) as specified in the following example:

```
<!-- Mapping of HTTP error codes and application exceptions to error pages -->
<error-page>
    <exception-type>UserValidationException</exception-type>
    <location>/errors/validationError.html</location>
</error-page>
<error-page>
    <error-code>500</error-code>
    <location>/errors/internalError.html</location>
</error-page>
...
</error-page> ...
```

RECOMMENDED JAVA TOOLS

The two main Java frameworks for server-side validation are:

[1] Jakarta Commons Validator (integrated with Struts 1.1)

The Jakarta Commons Validator is a Java framework that defines the error handling mechanism as described above. Validation rules are configured in an XML file that defines input validation rules for form fields and the corresponding validation error keys. Struts provides internationalization support to build localized applications using resource bundles and message formatting.

Example to validate the `userName` field of a loginForm using Struts Validator:

```
<form-validation>
    <global>
        ...
        <validator name="required" classname="org.apache.struts.validator.FieldChecks"
            method="validateRequired" msg="errors.required">
        </validator>
        <validator name="mask"
            classname="org.apache.struts.validator.FieldChecks"
            method="validateMask" msg="errors.invalid">
        </validator>
        ...
    </global>
    <formset>
        <form name="loginForm">
            <!-- userName is required and is alpha-numeric case insensitive -->
            <field property="userName" depends="required,mask">
                <!-- message resource key to display if validation fails -->
                <msg name="mask" key="login.userName.maskmsg"/>
                <arg0 key="login.userName.displayName"/>
                <var name="mask"/>
                <var-value>^[a-zA-Z0-9]*$</var-value>
            </field>
            ...
        </form>
    </formset>
</form-validation>
```

The Struts JSP tag library defines the `"errors"` tag that conditionally displays a set of accumulated error messages as shown in the following example:

```
<%@ page language="java" %>
<%@ taglib uri="/WEB-INF/struts-html.tld" prefix="html" %>
<%@ taglib uri="/WEB-INF/struts-bean.tld" prefix="bean" %>
<html:html>
    <head>
    <body>
        <html:form action="/logon.do">
            <table border="0" width="100%">
                <tr>
                    <th align="right"><html:errors property="username"/><bean:message key="prompt.username"/></th>
                    <td align="left"><html:text property="username" size="16"/></td>
                </tr>
                <tr>
                    <td align="right"><html:submit><bean:message key="button.submit"/></html:submit></td>
                    <td align="right"><html:reset><bean:message key="button.reset"/></html:reset></td>
                </tr>
            </table>
        </html:form>
    </body>
</html:html>
```

[2] JavaServer Faces Technology

JavaServer Faces Technology is a set of Java APIs (JSR 127) to represent UI components, manage their state, handle events, validate input, and support internationalization.

The JavaServer Faces API defines the `"output_errors"` `UIOutput` Renderer, which displays error messages for an entire page or error messages associated with a specified client identifier.

Example to validate the userName field of a loginForm using JavaServer Faces:

```
<%@ taglib uri="https://docs.oracle.com/javaee/6/tutorial/doc/glxce.html" prefix="h" %> <%@ taglib
uri="http://mrbool.com/how-to-create-a-login-validation-with-jsf-java-server-faces/27046" prefix="f" %> ... <jsp:useBean
id="UserBean" class="myApplication.UserBean" scope="session" /> <f:use_faces> <h:form formName="loginForm" >
<h:input_text id="userName" size="20" modelReference="UserBean.userName"> <f:validate_required/>
<f:validate_length minimum="8" maximum="20"/> </h:input_text> <!-- display errors if present --> <h:output_errors
id="loginErrors" clientId="userName"/> <h:command_button id="submit" label="Submit" commandName="submit" />
<p> </h:form> </f:use_faces>
```

**** Input Data Validation:**

While data validations may be provided as a user convenience on the client-tier, data validation must always be performed on the server-tier. Client-side validations are inherently insecure because they can be easily bypassed, e.g. by disabling Javascript.

A good design usually requires the web application framework to provide server-side utility routines to validate the following:

- [1] Required field
- [2] Field data type (all HTTP request parameters are Strings by default)
- [3] Field length
- [4] Field range
- [5] Field options
- [6] Field pattern
- [7] Cookie values
- [8] HTTP Response

A good practice is to implement a function or functions that validates each application parameter. The following sections describe some example checking.

[1] Required field

Always check that the field is not null and its length is greater than zero, excluding leading and trailing white spaces.

Example of how to validate required fields:

```
// PHP example to validate required fields function validateRequired($input) { ... $pass = false; if (strlen(trim($input))>0)
{ $pass = true; } return $pass; ... } ... if (validateRequired($fieldName)) { // fieldName is valid, continue processing
request ... }
```

[2] Field data type

In web applications, input parameters are poorly typed. For example, all HTTP request parameters or cookie values are of type String. The developer is responsible for verifying the input is of the correct data type.

[3] Field length

Always ensure that the input parameter (whether HTTP request parameter or cookie value) is bounded by a minimum length and/or a maximum length.

[4] Field range

Always ensure that the input parameter is within a range as defined by the functional requirements.

[5] Field options

Often, the web application presents the user with a set of options to choose from, e.g. using the SELECT HTML tag, but fails to perform server-side validation to ensure that the selected value is one of the allowed options. Remember that a malicious user can easily modify any option value. Always validate the selected user value against the allowed options as defined by the functional requirements.

[6] Field pattern

Always check that user input matches a pattern as defined by the functionality requirements. For example, if the userName field should only allow alpha-numeric characters, case insensitive, then use the following regular expression:

```
^[a-zA-Z0-9]+$
```

[7] Cookie value

The same validation rules (described above) apply to cookie values depending on the application requirements, e.g. validate a required value, validate length, etc.

[8] HTTP Response

[8-1] Filter user input

To guard the application against cross-site scripting, the developer should sanitize HTML by converting sensitive characters to their corresponding character entities. These are the HTML sensitive characters:

```
< > " ' % ; ) ( & +
```

PHP includes some automatic sanitization utility functions, such as htmlentities():

```
$input = htmlentities($input, ENT_QUOTES, 'UTF-8');
```

In addition, in order to avoid UTF-7 variants of Cross-site Scripting, you should explicitly define the Content-Type header of the response, for example:

```
<?php header('Content-Type: text/html; charset=UTF-8'); ?>
```

[8-2] Secure the cookie

When storing sensitive data in a cookie and transporting it over SSL, make sure that you first set the secure flag of the cookie in the HTTP response. This will instruct the browser to only use that cookie over SSL connections.

You can use the following code example, for securing the cookie:

```
<$php $value = "some_value"; $time = time()+3600; $path = "/application/"; $domain = ".example.com"; $secure = 1; setcookie("CookieName", $value, $time, $path, $domain, $secure, TRUE); ?>
```

In addition, we recommend that you use the HttpOnly flag. When the HttpOnly flag is set to TRUE the cookie will be made accessible only through the HTTP protocol. This means that the cookie won't be accessible by scripting languages, such as JavaScript. This setting can effectively help to reduce identity theft through XSS attacks (although it is not supported by all browsers).

The HttpOnly flag was Added in PHP 5.2.0.

C Blind SQL Injection

Cause

Sanitation of hazardous characters was not performed correctly on user input

Risk

It is possible to view, modify or delete database entries and tables

The software constructs all or part of an SQL command using externally-influenced input, but fails to neutralize elements that could modify the SQL command when it is sent to the database.

Without sufficient removal or quoting of SQL syntax in user-controllable inputs, the generated SQL query can cause those inputs to be interpreted as SQL instead of ordinary user data. This can be used to alter query logic to bypass security checks, or to insert additional statements that modify the back-end database, possibly including execution of system commands.

For example, let's say we have an HTML page with a login form, which eventually runs the following SQL query on the database using the user input:

```
SELECT * FROM accounts WHERE username='$user' AND password='$pass'
```

The two variables, \$user and \$pass, contain the user credentials entered by the user in the login form.

If the user has input "jsmith" as the username, and "Demo1234" as the password, the SQL query will look like this:

```
SELECT * FROM accounts WHERE username='jsmith' AND password='Demo1234'
```

But if the user input "'" (a single apostrophe) as the username, and "'" (a single apostrophe) as the password, the SQL query will look like this:

```
SELECT * FROM accounts WHERE username=''' AND password='''
```

This, of course, is a malformed SQL query, and will invoke an error message, which may be returned in the HTTP response.

An error such as this informs the attacker that an SQL Injection has succeeded, which will lead the attacker to attempt further attack vectors.

Blind SQL Injection is similar of SQL Injection. The difference lies in the fact that to leverage it, the attacker does not need to look for SQL errors in the response. Therefore, the method AppScan uses to identify it is also different.

Instead of attempting to invoke an SQL error, AppScan locates scripts that are susceptible to SQL injection, by manipulating the logic of the application through multiple requests.

The technique calls for sending requests whose vulnerable parameter (the parameter that gets embedded in the SQL query) is modified so that the response indicates whether the data is used in SQL query context or not. The modification involves the use of an AND Boolean expression with the original string, which evaluates once as True and once as False. In one case, the net result should be identical to the original result (a successful login), and in the other case, the result should be significantly different (a failed login). An OR expression which evaluates as True may also be useful for some rare cases.

If the original data is numeric, a simpler trick can be played. Let's consider original data 123. This can be replaced with 0+123 in one request, and with 456+123 in another. The result of the first request should be identical to the original result, whereas the result of the second request should be different (as the number is evaluated as 579). For some cases, we still need a version of the attack described above (using AND and OR), but without escaping from string context.

The concept behind Blind SQL Injection is that it is possible, even without receiving direct data from the database (in the

form of an error message, or leaked information), to extract data from the database, one bit at a time, or to modify the query in a malicious way. The idea is that the application's behavior (returning responses that are identical or different to the original response) can provide a single bit of information about the evaluated (modified) query, meaning, it's possible for the attacker to formulate an SQL Boolean expression whose evaluation (single bit) is compromised in the form of the application behavior (identical/un-identical to the original behavior).

Fix recommendation

There are several mitigation techniques:

[1] Strategy: Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness or provides constructs that make it easier to avoid.

[2] Strategy: Parameterization

If available, use structured mechanisms that automatically enforce separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this at every point where output is generated.

[3] Strategy: Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks.

[4] Strategy: Output Encoding

If you need to use dynamically-generated query strings or commands in spite of the risk, properly quote arguments, and escape any special characters within those arguments.

[5] Strategy: Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy: a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. Do not rely exclusively on detecting for malicious or malformed inputs with a blacklist. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Here are two possible ways to protect your web application against SQL injection attacks:

[1] Use a stored procedure rather than dynamically built SQL query string. The way parameters are passed to SQL Server stored procedures, prevents the use of apostrophes and hyphens.

Here is a simple example of how to use stored procedures in ASP.NET:

```
' Visual Basic example Dim DS As DataSet Dim MyConnection As SqlConnection Dim MyCommand As SqlDataAdapter Dim
SelectCommand As String = "select * from users where username = @username" ...
MyCommand.SelectCommand.Parameters.Add(New SqlParameter("@username", SqlDbType.NVarChar, 20))
MyCommand.SelectCommand.Parameters["@username"].Value = UserNameField.Value // C# example String selectCmd
= "select * from Authors where state = @username"; SqlConnection myConnection = new SqlConnection("server=...");
SqlDataAdapter myCommand = new SqlDataAdapter(selectCmd, myConnection);
MyCommand.SelectCommand.Parameters.Add(new SqlParameter("@username", SqlDbType.NVarChar, 20));
myCommand.SelectCommand.Parameters["@username"].Value = UserNameField.Value;
```

[2] You can add input validation to Web Forms pages by using validation controls. Validation controls provide an easy-to-use mechanism for all common types of standard validation - for example, testing for valid dates or values within a range - plus ways to provide custom-written validation. In addition, validation controls allow you to completely customize how error information is displayed to the user. Validation controls can be used with any controls that are processed in a Web Forms page's class file, including both HTML and Web server controls.

In order to make sure user input contains only valid values, you can use one of the following validation controls:

- a. "RangeValidator": checks that a user's entry (value) is between specified lower and upper boundaries. You can check ranges within pairs of numbers, alphabetic characters, and dates.
- b. "RegularExpressionValidator": checks that the entry matches a pattern defined by a regular expression. This type of validation allows you to check for predictable sequences of characters, such as those in social security numbers, e-mail addresses, telephone numbers, postal codes, and so on.

Important note: validation controls do not block user input or change the flow of page processing; they only set an error state, and produce error messages. It is the programmer's responsibility to test the state of the controls in the code before performing further application-specific actions.

There are two ways to check for user input validity:

1. Testing for a general error state:

In your code, test the page's IsValid property. This property rolls up the values of the IsValid properties of all the validation controls on the page (using a logical AND). If one of the validation controls is set to invalid, the page's property will return false.

2. Testing for the error state of individual controls:

Loop through the page's Validators collection, which contains references to all the validation controls. You can then examine the IsValid property of each validation control.

**** Prepared Statements:**

There are 3 possible ways to protect your application against SQL injection, i.e. malicious tampering of SQL parameters.

Instead of dynamically building SQL statements, use:

[1] `PreparedStatement`, which is precompiled and stored in a pool of `PreparedStatement` objects. `PreparedStatement` defines setters to register input parameters that are compatible with the supported JDBC SQL data types. For example, `setString` should be used for input parameters of type `VARCHAR` or `LONGVARCHAR` (refer to the Java API for further details). This way of setting input parameters prevents an attacker from manipulating the SQL statement through injection of bad characters, such as apostrophe.

Example of how to use a `PreparedStatement` in J2EE:

```
// J2EE PreparedStatement Example // Get a connection to the database
Connection myConnection; if (isDataSourceEnabled()) { // using the DataSource to get a managed connection
Context ctx = new InitialContext(); myConnection = ((DataSource)ctx.lookup(datasourceName)).getConnection(dbUserName, dbPassword); } else { try { // using the DriverManager to get a JDBC connection
Class.forName(jdbcDriverClassName); myConnection = DriverManager.getConnection(jdbcURL, dbUserName, dbPassword); } catch (ClassNotFoundException e) { ... } } ... try { PreparedStatement myStatement = myConnection.prepareStatement("select * from users where username = ?"); myStatement.setString(1, userNameField); ResultSet rs = myStatement.executeQuery(); ... rs.close(); } catch (SQLException sqlException) { ... } finally { myStatement.close(); myConnection.close(); }
```

[2] `CallableStatement`, which extends `PreparedStatement` to execute database SQL stored procedures. This class inherits input setters from `PreparedStatement` (see [1] above).

The following example assumes that this database stored procedure has been created:

```
CREATE PROCEDURE select_user (@username varchar(20))
AS SELECT * FROM USERS WHERE USERNAME = @username;
```

Example of how to use a `CallableStatement` in J2EE to execute the above stored procedure:

```
// J2EE CallableStatement Example // Get a connection to the database
Connection myConnection; if (isDataSourceEnabled()) { // using the DataSource to get a managed connection
Context ctx = new InitialContext(); myConnection = ((DataSource)ctx.lookup(datasourceName)).getConnection(dbUserName, dbPassword); } else { try { // using the DriverManager to get a JDBC connection
Class.forName(jdbcDriverClassName); myConnection = DriverManager.getConnection(jdbcURL, dbUserName, dbPassword); } catch (ClassNotFoundException e) { ... } } ... try { CallableStatement myStatement = myConnection.prepareCall("{?= call select_user ?,?}"); myStatement.setString(1, userNameField); myStatement.registerOutParameter(1, Types.VARCHAR); ResultSet rs = myStatement.executeQuery(); ... rs.close(); } catch (SQLException sqlException) { ... } finally { myStatement.close(); myConnection.close(); }
```

[3] `Entity Bean`, which represents an EJB business object in a persistent storage mechanism. There are two types of entity beans: bean-managed and container-managed. With bean-managed persistence, the developer is responsible of writing the SQL code to access the database (refer to sections [1] and [2] above). With container-managed persistence, the EJB container automatically generates the SQL code. As a result, the container is responsible of preventing malicious attempts to tamper with the generated SQL code.

Example of how to use an `Entity Bean` in J2EE:

```
// J2EE EJB Example try { // lookup the User home interface
UserHome userHome = (UserHome)context.lookup(User.class); // find the User remote interface
User = userHome.findByPrimaryKey(new UserKey(userNameField)); ... } catch (Exception e) { ... }
```

** Input Data Validation:

While data validations may be provided as a user convenience on the client-tier, data validation must be performed on the server-tier using Servlets. Client-side validations are inherently insecure because they can be easily bypassed, e.g. by disabling Javascript.

A good design usually requires the web application framework to provide server-side utility routines to validate the following:

- [1] Required field
- [2] Field data type (all HTTP request parameters are Strings by default)
- [3] Field length
- [4] Field range
- [5] Field options
- [6] Field pattern
- [7] Cookie values
- [8] HTTP Response

A good practice is to implement the above routine as static methods in a "Validator" utility class. The following sections describe an example validator class.

[1] Required field

Always check that the field is not null and its length is greater than zero, excluding leading and trailing white spaces.

Example of how to validate required fields:

```
// Java example to validate required fields public Class Validator { ... public static boolean validateRequired(String value)
{ boolean isValid = false; if (value != null && value.trim().length() > 0) { isValid = true; } return isValid; }
... } ... String fieldValue = request.getParameter("fieldName"); if (Validator.validateRequired(fieldValue)) { // fieldValue is
valid, continue processing request ... }
```

[2] Field data type

In web applications, input parameters are poorly typed. For example, all HTTP request parameters or cookie values are of type String. The developer is responsible for verifying the input is of the correct data type. Use the Java primitive wrapper classes to check if the field value can be safely converted to the desired primitive data type.

Example of how to validate a numeric field (type int):

```
// Java example to validate that a field is an int number public Class Validator { ... public static boolean validateInt(String
value) { boolean isValid = false; try { Integer.parseInt(value); isValid = true; } catch (Exception e) { isValid
= false; } return isValid; } ... } ... // check if the HTTP request parameter is of type int String fieldValue =
request.getParameter("fieldName"); if (Validator.validateInt(fieldValue)) { // fieldValue is valid, continue processing
request ... }
```

A good practice is to convert all HTTP request parameters to their respective data types. For example, the developer should store the "integerValue" of a request parameter in a request attribute and use it as shown in the following example:

```
// Example to convert the HTTP request parameter to a primitive wrapper data type // and store this value in a request
attribute for further processing String fieldValue = request.getParameter("fieldName"); if
(Validator.validateInt(fieldValue)) { // convert fieldValue to an Integer Integer integerValue =
Integer.parseInt(fieldValue); // store integerValue in a request attribute request.setAttribute("fieldName",
integerValue); } ... // Use the request attribute for further processing Integer integerValue =
(Integer)request.getAttribute("fieldName"); ...
```

The primary Java data types that the application should handle:

- Byte
- Short
- Integer
- Long
- Float
- Double
- Date

[3] Field length

Always ensure that the input parameter (whether HTTP request parameter or cookie value) is bounded by a minimum length and/or a maximum length.

Example to validate that the length of the userName field is between 8 and 20 characters:

```
// Example to validate the field length public Class Validator { ... public static boolean validateLength(String value, int
minLength, int maxLength) { String validatedValue = value; if (!validateRequired(value)) { validatedValue = ""; } return
(validatedValue.length() >= minLength && validatedValue.length() <= maxLength); } ... } ... String userName =
request.getParameter("userName"); if (Validator.validateRequired(userName)) { if (Validator.validateLength(userName,
8, 20)) { // userName is valid, continue further processing ... } }
```

[4] Field range

Always ensure that the input parameter is within a range as defined by the functional requirements.

Example to validate that the input numberOfChoices is between 10 and 20:

```
// Example to validate the field range public Class Validator { ... public static boolean validateRange(int value, int min, int
max) { return (value >= min && value <= max); } ... } ... String fieldValue = request.getParameter("numberOfChoices");
if (Validator.validateRequired(fieldValue)) { if (Validator.validateInt(fieldValue)) { int numberOfChoices =
Integer.parseInt(fieldValue); if (Validator.validateRange(numberOfChoices, 10, 20)) { // numberOfChoices is valid,
continue processing request ... } } }
```

[5] Field options

Often, the web application presents the user with a set of options to choose from, e.g. using the SELECT HTML tag, but fails to perform server-side validation to ensure that the selected value is one of the allowed options. Remember that a malicious user can easily modify any option value. Always validate the selected user value against the allowed options as defined by the functional requirements.

Example to validate the user selection against a list of allowed options:

```
// Example to validate user selection against a list of options public Class Validator { ... public static boolean
```

```
validateOption(Object[] options, Object value) { boolean isValidValue = false; try { List list = Arrays.asList(options); if (list != null) { isValidValue = list.contains(value); } } catch (Exception e) { } return isValidValue; } ... } ... // Allowed options
String[] options = {"option1", "option2", "option3"}; // Verify that the user selection is one of the allowed options String
userSelection = request.getParameter("userSelection"); if (Validator.validateOption(options, userSelection)) { // valid
user selection, continue processing request ... }
```

[6] Field pattern

Always check that the user input matches a pattern as defined by the functionality requirements. For example, if the userName field should only allow alpha-numeric characters, case insensitive, then use the following regular expression:

```
^[a-zA-Z0-9]*$
```

Java 1.3 or earlier versions do not include any regular expression packages. Apache Regular Expression Package (see Resources below) is recommended for use with Java 1.3 to resolve this lack of support. Example to perform regular expression validation:

```
// Example to validate that a given value matches a specified pattern // using the Apache regular expression package
import org.apache.regexp.RE; import org.apache.regexp.RESyntaxException; public Class Validator { ... public static
boolean matchPattern(String value, String expression) { boolean match = false; if (validateRequired(expression)) { RE r
= new RE(expression); match = r.match(value); } return match; } ... } ... // Verify that the userName request parameter
is alpha-numeric String userName = request.getParameter("userName"); if (Validator.matchPattern(userName, "^[a-zA-
Z0-9]*$")) { // userName is valid, continue processing request ... }
```

Java 1.4 introduced a new regular expression package (java.util.regex). Here is a modified version of Validator.matchPattern using the new Java 1.4 regular expression package:

```
// Example to validate that a given value matches a specified pattern // using the Java 1.4 regular expression package
import java.util.regex.Pattern; import java.util.regex.Matcher; public Class Validator { ... public static boolean
matchPattern(String value, String expression) { boolean match = false; if (validateRequired(expression)) { match =
Pattern.matches(expression, value); } return match; } ... }
```

[7] Cookie value

Use the javax.servlet.http.Cookie object to validate the cookie value. The same validation rules (described above) apply to cookie values depending on the application requirements, e.g. validate a required value, validate length, etc.

Example to validate a required cookie value:

```
// Example to validate a required cookie value // First retrieve all available cookies submitted in the HTTP request Cookie[]
cookies = request.getCookies(); if (cookies != null) { // find the "user" cookie for (int i=0; i<cookies.length; ++i) { if
(cookies[i].getName().equals("user")) { // validate the cookie value if (Validator.validateRequired(cookies[i].getValue())) {
// valid cookie value, continue processing request ... } } }
```

[8] HTTP Response

[8-1] Filter user input

To guard the application against cross-site scripting, sanitize HTML by converting sensitive characters to their corresponding character entities. These are the HTML sensitive characters:

```
< > " ' % ; ) ( & +
```

Example to filter a specified string by converting sensitive characters to their corresponding character entities:

```
// Example to filter sensitive data to prevent cross-site scripting public Class Validator { ... public static String filter(String
value) { if (value == null) { return null; } StringBuffer result = new StringBuffer(value.length()); for (int i=0;
i<value.length(); ++i) { switch (value.charAt(i)) { case '<': result.append("<"); break; case '>': result.append(">");
break; case '"': result.append("""); break; case ''': result.append("'"); break; case '%': result.append("%"); break; case ';':
result.append(";"); break; case '(': result.append("("); break; case ')': result.append(")"); break; case '&':
result.append("&"); break; case '+': result.append("+"); break; default: result.append(value.charAt(i)); break; } return
result; } ... } ... // Filter the HTTP response using Validator.filter PrintWriter out = response.getWriter(); // set output
response out.write(Validator.filter(response)); out.close();
```

The Java Servlet API 2.3 introduced Filters, which supports the interception and transformation of HTTP requests or responses.

Example of using a Servlet Filter to sanitize the response using Validator.filter:

```
// Example to filter all sensitive characters in the HTTP response using a Java Filter. // This example is for illustration
purposes since it will filter all content in the response, including HTML tags! public class SensitiveCharsFilter implements
Filter { ... public void doFilter(ServletRequest request, ServletResponse response, FilterChain chain) throws IOException,
ServletException { PrintWriter out = response.getWriter(); ResponseWrapper wrapper = new
ResponseWrapper(HttpServletResponse response); chain.doFilter(request, wrapper); CharArrayWriter caw = new
CharArrayWriter(); caw.write(Validator.filter(wrapper.toString())); response.setContentType("text/html");
response.setContentLength(caw.toString().length()); out.write(caw.toString()); out.close(); } ... public class
CharResponseWrapper extends HttpServletResponseWrapper { private CharArrayWriter output; public String toString() {
return output.toString(); } public CharResponseWrapper(HttpServletResponse response) { super(response); output = new
CharArrayWriter(); } public PrintWriter getWriter() { return new PrintWriter(output); } } }
```

[8-2] Secure the cookie

When storing sensitive data in a cookie, make sure to set the secure flag of the cookie in the HTTP response, using Cookie.setSecure(boolean flag) to instruct the browser to send the cookie using a secure protocol, such as HTTPS or SSL.

Example to secure the "user" cookie:

```
// Example to secure a cookie, i.e. instruct the browser to // send the cookie using a secure protocol Cookie cookie = new
Cookie("user", "sensitive"); cookie.setSecure(true); response.addCookie(cookie);
```

RECOMMENDED JAVA TOOLS

The two main Java frameworks for server-side validation are:

[1] Jakarta Commons Validator (integrated with Struts 1.1)

The Jakarta Commons Validator is a powerful framework that implements all the above data validation requirements. These rules are configured in an XML file that defines input validation rules for form fields. Struts supports output filtering of dangerous characters in the [8] HTTP Response by default on all data written using the Struts 'bean:write' tag. This filtering may be disabled by setting the 'filter=false' flag.

Struts defines the following basic input validators, but custom validators may also be defined:

required: succeeds if the field contains any characters other than white space.

mask: succeeds if the value matches the regular expression given by the mask attribute.

range: succeeds if the value is within the values given by the min and max attributes ((value >= min) & (value <= max)).

maxLength: succeeds if the field is length is less than or equal to the max attribute.

minLength: succeeds if the field is length is greater than or equal to the min attribute.

byte, short, integer, long, float, double: succeeds if the value can be converted to the corresponding primitive.

date: succeeds if the value represents a valid date. A date pattern may be provided.

creditCard: succeeds if the value could be a valid credit card number.

e-mail: succeeds if the value could be a valid e-mail address.

Example to validate the userName field of a loginForm using Struts Validator:

```
<form-validation> <global> ... <validator name="required" classname="org.apache.struts.validator.FieldChecks"
method="validateRequired" msg="errors.required"> </validator> <validator name="mask"
classname="org.apache.struts.validator.FieldChecks" method="validateMask" msg="errors.invalid"> </validator> ...
</global> <formset> <form name="loginForm"> <!-- userName is required and is alpha-numeric case insensitive -->
<field property="userName" depends="required,mask"> <!-- message resource key to display if validation fails -->
<msg name="mask" key="login.userName.maskmsg"/> <arg0 key="login.userName.displayName"/> <var> <var-
name>mask</var-name> <var-value>^[a-zA-Z0-9]*$</var-value> </var> </field> ... </form> ... </formset> </form-
validation>
```

[2] JavaServer Faces Technology

JavaServer Faces Technology is a set of Java APIs (JSR 127) to represent UI components, manage their state, handle events and input validation.

The JavaServer Faces API implements the following basic validators, but custom validators may be defined:

validate_doublerange: registers a DoubleRangeValidator on a component

validate_length: registers a LengthValidator on a component

validate_longrange: registers a LongRangeValidator on a component

validate_required: registers a RequiredValidator on a component

validate_stringrange: registers a StringRangeValidator on a component

validator: registers a custom Validator on a component

The JavaServer Faces API defines the following UIInput and UIOutput Renderers (Tags):

input_date: accepts a java.util.Date formatted with a java.text.Date instance

output_date: displays a java.util.Date formatted with a java.text.Date instance

input_datetime: accepts a java.util.Date formatted with a java.text.DateTime instance

output_datetime: displays a java.util.Date formatted with a java.text.DateTime instance

input_number: displays a numeric data type (java.lang.Number or primitive), formatted with a java.text.NumberFormat

output_number: displays a numeric data type (java.lang.Number or primitive), formatted with a java.text.NumberFormat

input_text: accepts a text string of one line.

output_text: displays a text string of one line.

input_time: accepts a java.util.Date, formatted with a java.text.DateFormat time instance

output_time: displays a java.util.Date, formatted with a java.text.DateFormat time instance

input_hidden: allows a page author to include a hidden variable in a page

input_secret: accepts one line of text with no spaces and displays it as a set of asterisks as it is typed

input_textarea: accepts multiple lines of text

output_errors: displays error messages for an entire page or error messages associated with a specified client identifier

output_label: displays a nested component as a label for a specified input field

output_message: displays a localized message

Example to validate the userName field of a loginForm using JavaServer Faces:

```
<%@ taglib uri="https://docs.oracle.com/javaee/6/tutorial/doc/glxce.html" prefix="h" %> <%@ taglib
uri="http://mrbool.com/how-to-create-a-login-validation-with-jsf-java-server-faces/27046" prefix="f" %> ... <jsp:useBean
id="UserBean" class="myApplication.UserBean" scope="session" /> <f:use_faces> <h:form formName="loginForm" >
<h:input_text id="userName" size="20" modelReference="UserBean.userName"> <f:validate_required/>
<f:validate_length minimum="8" maximum="20"/> </h:input_text> <!-- display errors if present --> <h:output_errors
id="loginErrors" clientId="userName"/> <h:command_button id="submit" label="Submit" commandName="submit" />
<p> </h:form> </f:use_faces>
```

**** Error Handling:**

Many J2EE web application architectures follow the Model View Controller (MVC) pattern. In this pattern a Servlet acts as a Controller. A Servlet delegates the application processing to a JavaBean such as an EJB Session Bean (the Model). The Servlet then forwards the request to a JSP (View) to render the processing results. Servlets should check all input, output, return codes, error codes and known exceptions to ensure that the expected processing actually occurred.

While data validation protects applications against malicious data tampering, a sound error handling strategy is necessary to prevent the application from inadvertently disclosing internal error messages such as exception stack traces. A good error handling strategy addresses the following items:

[1] Defining Errors

[2] Reporting Errors

[3] Rendering Errors

[4] Error Mapping

[1] Defining Errors

Hard-coded error messages in the application layer (e.g. Servlets) should be avoided. Instead, the application should use error keys that map to known application failures. A good practice is to define error keys that map to validation rules for HTML form fields or other bean properties. For example, if the "user_name" field is required, is alphanumeric, and must be unique in the database, then the following error keys should be defined:

(a) ERROR_USERNAME_REQUIRED: this error key is used to display a message notifying the user that the "user_name" field is required;

(b) ERROR_USERNAME_ALPHANUMERIC: this error key is used to display a message notifying the user that the "user_name" field should be alphanumeric;

(c) ERROR_USERNAME_DUPLICATE: this error key is used to display a message notifying the user that the "user_name" value is a duplicate in the database;

(d) ERROR_USERNAME_INVALID: this error key is used to display a generic message notifying the user that the

"user_name" value is invalid;

A good practice is to define the following framework Java classes which are used to store and report application errors:

- ErrorKeys: defines all error keys

```
// Example: ErrorKeys defining the following error keys: // - ERROR_USERNAME_REQUIRED // -
ERROR_USERNAME_ALPHANUMERIC // - ERROR_USERNAME_DUPLICATE // - ERROR_USERNAME_INVALID // ... public Class
ErrorKeys { public static final String ERROR_USERNAME_REQUIRED = "error.username.required"; public static final String
ERROR_USERNAME_ALPHANUMERIC = "error.username.alphanumeric"; public static final String
ERROR_USERNAME_DUPLICATE = "error.username.duplicate"; public static final String ERROR_USERNAME_INVALID =
"error.username.invalid"; ... }
```

- Error: encapsulates an individual error

```
// Example: Error encapsulates an error key. // Error is serializable to support code executing in multiple JVMs. public
Class Error implements Serializable { // Constructor given a specified error key public Error(String key) { this(key, null); }
// Constructor given a specified error key and array of placeholder objects public Error(String key, Object[] values) {
this.key = key; this.values = values; } // Returns the error key public String getKey() { return this.key; } // Returns the
placeholder values public Object[] getValues() { return this.values; } private String key = null; private Object[] values =
null; }
```

- Errors: encapsulates a Collection of errors

```
// Example: Errors encapsulates the Error objects being reported to the presentation layer. // Errors are stored in a
HashMap where the key is the bean property name and value is an // ArrayList of Error objects. public Class Errors
implements Serializable { // Adds an Error object to the Collection of errors for the specified bean property. public void
addError(String property, Error error) { ArrayList propertyErrors = (ArrayList)errors.get(property); if (propertyErrors ==
null) { propertyErrors = new ArrayList(); errors.put(property, propertyErrors); } propertyErrors.put(error); } // Returns
true if there are any errors public boolean hasErrors() { return (errors.size > 0); } // Returns the Errors for the specified
property public ArrayList getErrors(String property) { return (ArrayList)errors.get(property); } private HashMap errors =
new HashMap(); }
```

Using the above framework classes, here is an example to process validation errors of the "user_name" field:

```
// Example to process validation errors of the "user_name" field. Errors errors = new Errors(); String userName =
request.getParameter("user_name"); // (a) Required validation rule if (!Validator.validateRequired(userName)) {
errors.addError("user_name", new Error(ErrorKeys.ERROR_USERNAME_REQUIRED)); } // (b) Alpha-numeric validation rule
else if (!Validator.matchPattern(userName, "^[a-zA-Z0-9]*$")) { errors.addError("user_name", new
Error(ErrorKeys.ERROR_USERNAME_ALPHANUMERIC)); } else { // (c) Duplicate check validation rule // We assume that
there is an existing UserValidationEJB session bean that implements // a checkIfDuplicate() method to verify if the user
already exists in the database. try { ... if (UserValidationEJB.checkIfDuplicate(userName)) { errors.addError("user_name",
new Error(ErrorKeys.ERROR_USERNAME_DUPLICATE)); } } catch (RemoteException e) { // log the error
logger.error("Could not validate user for specified userName: " + userName); errors.addError("user_name", new
Error(ErrorKeys.ERROR_USERNAME_DUPLICATE)); } } // set the errors object in a request attribute called "errors"
request.setAttribute("errors", errors); ...
```

[2] Reporting Errors

There are two ways to report web-tier application errors:

(a) Servlet Error Mechanism

(b) JSP Error Mechanism

[2-a] Servlet Error Mechanism

A Servlet may report errors by:

- forwarding to the input JSP (having already stored the errors in a request attribute), OR
- calling response.sendError with an HTTP error code argument, OR
- throwing an exception

It is good practice to process all known application errors (as described in section [1]), store them in a request attribute, and forward to the input JSP. The input JSP should display the error messages and prompt the user to re-enter the data. The following example illustrates how to forward to an input JSP (userInput.jsp):

```
// Example to forward to the userInput.jsp following user validation errors RequestDispatcher rd =
getServletContext().getRequestDispatcher("/user/userInput.jsp"); if (rd != null) { rd.forward(request, response); }
```

If the Servlet cannot forward to a known JSP page, the second option is to report an error using the response.sendError method with HttpServletResponse.SC_INTERNAL_SERVER_ERROR (status code 500) as argument. Refer to the javadoc of javax.servlet.http.HttpServletResponse for more details on the various HTTP status codes. Example to return a HTTP error:

```
// Example to return a HTTP error code RequestDispatcher rd =
getServletContext().getRequestDispatcher("/user/userInput.jsp"); if (rd == null) { // messages is a resource bundle with
all message keys and values response.sendError(HttpServletResponse.SC_INTERNAL_SERVER_ERROR,
messages.getMessage(ErrorKeys.ERROR_USERNAME_INVALID)); }
```

As a last resort, Servlets can throw an exception, which must be a subclass of one of the following classes:

- RuntimeException
- ServletException
- IOException

[2-b] JSP Error Mechanism

JSP pages provide a mechanism to handle runtime exceptions by defining an `errorPage` directive as shown in the following example:

```
<%@ page errorPage="/errors/userValidation.jsp" %>
```

Uncaught JSP exceptions are forwarded to the specified `errorPage`, and the original exception is set in a request parameter called `javax.servlet.jsp.jspException`. The error page must include a `isErrorPage` directive as shown below:

```
<%@ page isErrorPage="true" %>
```

The `isErrorPage` directive causes the "exception" variable to be initialized to the exception object being thrown.

[3] Rendering Errors

The J2SE Internationalization APIs provide utility classes for externalizing application resources and formatting messages including:

(a) Resource Bundles

(b) Message Formatting

[3-a] Resource Bundles

Resource bundles support internationalization by separating localized data from the source code that uses it. Each resource bundle stores a map of key/value pairs for a specific locale.

It is common to use or extend `java.util.PropertyResourceBundle`, which stores the content in an external properties file as shown in the following example:

```
##### # ErrorMessages.properties
##### # required user name error message
error.username.required=User name field is required # invalid user name format error.username.alphanumeric=User
name must be alphanumeric # duplicate user name error message error.username.duplicate=User name {0} already
exists, please choose another one ...
```

Multiple resources can be defined to support different locales (hence the name resource bundle). For example, `ErrorMessages_fr.properties` can be defined to support the French member of the bundle family. If the resource member of the requested locale does not exist, the default member is used. In the above example, the default resource is `ErrorMessages.properties`. Depending on the user's locale, the application (JSP or Servlet) retrieves content from the appropriate resource.

[3-b] Message Formatting

The J2SE standard class `java.util.MessageFormat` provides a generic way to create messages with replacement placeholders. A `MessageFormat` object contains a pattern string with embedded format specifiers as shown below:

```
// Example to show how to format a message using placeholder parameters String pattern = "User name {0} already
exists, please choose another one"; String userName = request.getParameter("user_name"); Object[] args = new
Object[1]; args[0] = userName; String message = MessageFormat.format(pattern, args);
```

Here is a more comprehensive example to render error messages using `ResourceBundle` and `MessageFormat`:

```
// Example to render an error message from a localized ErrorMessages resource (properties file) // Utility class to retrieve
locale-specific error messages public Class ErrorMessageResource { // Returns the error message for the specified error
key in the environment locale public String getErrorMessage(String errorKey) { return getErrorMessage(errorKey,
defaultLocale); } // Returns the error message for the specified error key in the specified locale public String
getErrorMessage(String errorKey, Locale locale) { return getErrorMessage(errorKey, null, locale); } // Returns a formatted
error message for the specified error key in the specified locale public String getErrorMessage(String errorKey, Object[]
args, Locale locale) { // Get localized ErrorMessageResource ResourceBundle errorMessageResource =
ResourceBundle.getBundle("ErrorMessages", locale); // Get localized error message String errorMessage =
errorMessageResource.getString(errorKey); if (args != null) { // Format the message using the specified placeholders
args return MessageFormat.format(errorMessage, args); } else { return errorMessage; } } // default environment locale
private Locale defaultLocale = Locale.getDefaultLocale(); } ... // Get the user's locale Locale userLocale =
request.getLocale(); // Check if there were any validation errors Errors errors = (Errors)request.getAttribute("errors"); if
(errors != null && errors.hasErrors()) { // iterate through errors and output error messages corresponding to the
"user_name" property ArrayList userNameErrors = errors.getErrors("user_name"); ListIterator iterator =
userNameErrors.iterator(); while (iterator.hasNext()) { // Get the next error object Error error = (Error)iterator.next();
String errorMessage = ErrorMessageResource.getErrorMessage(error.getKey(), userLocale); output.write(errorMessage +
"\r\n"); } }
```

It is recommended to define a custom JSP tag, e.g. `displayErrors`, to iterate through and render error messages as shown in the above example.

[4] Error Mapping

Normally, the Servlet Container will return a default error page corresponding to either the response status code or the exception. A mapping between the status code or the exception and a web resource may be specified using custom error pages. It is a good practice to develop static error pages that do not disclose internal error states (by default, most Servlet containers will report internal error messages). This mapping is configured in the Web Deployment Descriptor (`web.xml`) as specified in the following example:

```
<!-- Mapping of HTTP error codes and application exceptions to error pages --> <error-page> <exception-
type>UserValidationException</exception-type> <location>/errors/validationError.html</error-page> </error-page>
<error-page> <error-code>500</error-code> <location>/errors/internalError.html</error-page> </error-page>
<error-page> ... </error-page> ...
```

RECOMMENDED JAVA TOOLS

The two main Java frameworks for server-side validation are:

[1] Jakarta Commons Validator (integrated with Struts 1.1)

The Jakarta Commons Validator is a Java framework that defines the error handling mechanism as described above. Validation rules are configured in an XML file that defines input validation rules for form fields and the corresponding validation error keys. Struts provides internationalization support to build localized applications using resource bundles and message formatting.

Example to validate the userName field of a loginForm using Struts Validator:

```
<form-validation> <global> ... <validator name="required" classname="org.apache.struts.validator.FieldChecks"
method="validateRequired" msg="errors.required"> </validator> <validator name="mask"
classname="org.apache.struts.validator.FieldChecks" method="validateMask" msg="errors.invalid"> </validator> ...
</global> <formset> <form name="loginForm"> <!-- userName is required and is alpha-numeric case insensitive -->
<field property="userName" depends="required,mask"> <!-- message resource key to display if validation fails -->
<msg name="mask" key="login.userName.maskmsg"/> <arg0 key="login.userName.displayName"/> <var> <var-
name>mask</var-name> <var-value>^[a-zA-Z0-9]*$</var-value> </var> </field> ... </form> ... </formset> </form-
validation>
```

The Struts JSP tag library defines the "errors" tag that conditionally displays a set of accumulated error messages as shown in the following example:

```
<%@ page language="java" %> <%@ taglib uri="/WEB-INF/struts-html.tld" prefix="html" %> <%@ taglib uri="/WEB-
INF/struts-bean.tld" prefix="bean" %> <html:html> <head> <body> <html:form action="/logon.do"> <table
border="0" width="100%"> <tr> <th align="right"> <html:errors property="username"/> <bean:message
key="prompt.username"/> </th> <td align="left"> <html:text property="username" size="16"/> </td> </tr> <tr> <td
align="right"> <html:submit><bean:message key="button.submit"/></html:submit> </td> <td align="right">
<html:reset><bean:message key="button.reset"/></html:reset> </td> </tr> </table> </html:form> </body>
</html:html>
```

[2] JavaServer Faces Technology

JavaServer Faces Technology is a set of Java APIs (JSR 127) to represent UI components, manage their state, handle events, validate input, and support internationalization.

The JavaServer Faces API defines the "output_errors" UIOutput Renderer, which displays error messages for an entire page or error messages associated with a specified client identifier.

Example to validate the userName field of a loginForm using JavaServer Faces:

```
<%@ taglib uri="https://docs.oracle.com/javaee/6/tutorial/doc/glxce.html" prefix="h" %> <%@ taglib
uri="http://mrbool.com/how-to-create-a-login-validation-with-jsf-java-server-faces/27046" prefix="f" %> ... <jsp:useBean
id="UserBean" class="myApplication.UserBean" scope="session" /> <f:use_faces> <h:form formName="loginForm">
<h:input_text id="userName" size="20" modelReference="UserBean.userName"> <f:validate_required/>
<f:validate_length minimum="8" maximum="20"/> </h:input_text> <!-- display errors if present --> <h:output_errors
id="loginErrors" clientId="userName"/> <h:command_button id="submit" label="Submit" commandName="submit" />
<p> </h:form> </f:use_faces>
```

**** Filter User Input**

Before passing any data to a SQL query, it should always be properly filtered with whitelisting techniques. This cannot be

over-emphasized. Filtering user input will correct many injection flaws before they arrive at the database.

**** Quote User Input**

Regardless of data type, it is always a good idea to place single quotes around all user data if this is permitted by the database. MySQL allows this formatting technique.

**** Escape the Data Values**

If you're using MySQL 4.3.0 or newer, you should escape all strings with `mysql_real_escape_string()`. If you are using an older version of MySQL, you should use the `mysql_escape_string()` function. If you are not using MySQL, you might choose to use the specific escaping function for your particular database. If you are not aware of an escaping function, you might choose to utilize a more generic escaping function such as `addslashes()`.

If you're using the PEAR DB database abstraction layer, you can use the `DB::quote()` method or use a query placeholder like `?`, which automatically escapes the value that replaces the placeholder.

**** Input Data Validation:**

While data validations may be provided as a user convenience on the client-tier, data validation must always be performed on the server-tier. Client-side validations are inherently insecure because they can be easily bypassed, e.g. by disabling Javascript.

A good design usually requires the web application framework to provide server-side utility routines to validate the following:

- [1] Required field
- [2] Field data type (all HTTP request parameters are Strings by default)
- [3] Field length
- [4] Field range
- [5] Field options
- [6] Field pattern
- [7] Cookie values
- [8] HTTP Response

A good practice is to implement a function or functions that validates each application parameter. The following sections describe some example checking.

[1] Required field

Always check that the field is not null and its length is greater than zero, excluding leading and trailing white spaces.

Example of how to validate required fields:

```
// PHP example to validate required fields function validateRequired($input) { ... $pass = false; if (strlen(trim($input))>0) { $pass = true; } return $pass; ... } ... if (validateRequired($fieldName)) { // fieldName is valid, continue processing request ... }
```

[2] Field data type

In web applications, input parameters are poorly typed. For example, all HTTP request parameters or cookie values are of type String. The developer is responsible for verifying the input is of the correct data type.

[3] Field length

Always ensure that the input parameter (whether HTTP request parameter or cookie value) is bounded by a minimum length and/or a maximum length.

[4] Field range

Always ensure that the input parameter is within a range as defined by the functional requirements.

[5] Field options

Often, the web application presents the user with a set of options to choose from, e.g. using the SELECT HTML tag, but

fails to perform server-side validation to ensure that the selected value is one of the allowed options. Remember that a malicious user can easily modify any option value. Always validate the selected user value against the allowed options as defined by the functional requirements.

[6] Field pattern

Always check that user input matches a pattern as defined by the functionality requirements. For example, if the `userName` field should only allow alpha-numeric characters, case insensitive, then use the following regular expression:

```
^[a-zA-Z0-9]+$
```

[7] Cookie value

The same validation rules (described above) apply to cookie values depending on the application requirements, e.g. validate a required value, validate length, etc.

[8] HTTP Response

[8-1] Filter user input

To guard the application against cross-site scripting, the developer should sanitize HTML by converting sensitive characters to their corresponding character entities. These are the HTML sensitive characters:

```
< > " ' % ; ) ( & +
```

PHP includes some automatic sanitization utility functions, such as `htmlspecialchars()`:

```
$input = htmlspecialchars($input, ENT_QUOTES, 'UTF-8');
```

In addition, in order to avoid UTF-7 variants of Cross-site Scripting, you should explicitly define the Content-Type header of the response, for example:

```
<?php header('Content-Type: text/html; charset=UTF-8'); ?>
```

[8-2] Secure the cookie

When storing sensitive data in a cookie and transporting it over SSL, make sure that you first set the secure flag of the cookie in the HTTP response. This will instruct the browser to only use that cookie over SSL connections.

You can use the following code example, for securing the cookie:

```
<$php $value = "some_value"; $time = time()+3600; $path = "/application/"; $domain = ".example.com"; $secure = 1; setcookie("CookieName", $value, $time, $path, $domain, $secure, TRUE); ?>
```

In addition, we recommend that you use the `HttpOnly` flag. When the `HttpOnly` flag is set to `TRUE` the cookie will be made accessible only through the HTTP protocol. This means that the cookie won't be accessible by scripting languages, such as JavaScript. This setting can effectively help to reduce identity theft through XSS attacks (although it is not supported by all browsers).

The `HttpOnly` flag was Added in PHP 5.2.0.

[Go to Table of Contents](#)

Cause

Cookies are created at the client side

Risk

The worst case scenario for this attack depends on the context and role of the cookies that are created at the client side

A cookie is a piece of information usually created by the Web server and stored in the Web browser.

The cookie contains information used by web applications mainly (but not only) to identify users and maintain their state.

AppScan detected that the JavaScript code at the client side is used to manipulate (either create or modify) the site's cookies.

It is possible for an attacker to view this code, understand its logic, and use it to compose his own cookies, or modify existing ones, based on this knowledge.

The damage an attacker may cause depends on how the application uses its cookies, or what information it stores in them.

Among other things, cookie manipulation may lead to session hijacking or privilege escalation.

Other vulnerabilities caused by cookie poisoning contain SQL injection and Cross-Site scripting.

Fix recommendation

[1] Avoid placing business/security logic at the client side.

[2] Find and remove insecure client-side Javascript code which may pose a security threat to the site.

CWE

602

External references

- [WASC Threat Classification: Information Leakage](#)

[Go to Table of Contents](#)

M Cross-Site Request Forgery

Cause

This vulnerability arises because the application allows the user to perform some sensitive action without verifying that the request was sent intentionally.

An attacker can cause a victim's browser to emit an HTTP request to an arbitrary URL in the application. When this request is sent from an authenticated victim's browser, it will include the victim's session cookie or authentication header. The application will accept this as a valid request from an authenticated user.

When a web server is designed to receive a request from a client without any mechanism for verifying that it was intentionally sent, an attacker may be able to trick a client into making an unintentional request from a different site, which will be treated as an authentic request by the application. This can be done by submitting a form, loading an image, sending an XMLHttpRequest in JavaScript, and more.

For example, this IMG tag can be embedded in an attacker's webpage, and the victim's browser will submit a request to retrieve the image. This valid request will be processed by the application, and the browser will not display a broken image. `

Risk

An attacker can exploit this vulnerability to perform sensitive actions in another user's account, or using their privileges.

It may be possible to force an end-user to execute unwanted actions on a web application in which they're currently authenticated. This would allow the attacker to alter user records and to perform transactions as that user.

If the user is currently logged-in to the victim site, the request will automatically use the user's credentials such as session cookies, IP address, and other browser authentication methods. Using this method, the attacker forges the victim's identity and submits actions on their behalf.

The severity of this vulnerability depends on the affected functionality in context of the application. For example, a CSRF attack on a search page is less severe than a CSRF attack on a money-transfer or profile-update page.

Fix recommendation

Set all session and authentication cookies to include the `SameSite` attribute, setting it to `Strict` or `Lax`. When setting this attribute to `Lax` ensure that no sensitive action can be performed via a `GET` request, as per the HTTP standard.

Use built-in CSRF protection provided by the platform or framework, and ensure to activate it appropriately whether in configuration or code.

If your platform does not provide a built-in anti-CSRF mechanism, consider integrating a well-vetted library to implement the protection, such as OWASP CSRFGuard.

Avoid building a custom anti-CSRF implementation, as this can be complicated to achieve correctly without allowing trivial bypass. If you absolutely must do so due to lack of standard library support, you should generate a secure, random and non-predictable token (e.g. GUID v4) on the server and embed it in each HTML form, while binding it to the user's session. Upon receiving the submitted form, verify that the included form token matches the token previously bound to the user. It is also feasible to embed the CSRF token in a designated cookie ('double-submitted cookie'), or even better use a custom request header - when the server receives these together with the submitted form token, it is simple to validate that they match (instead of storing in the user's session).

An alternative approach would be to require user reauthentication for specific actions, to ensure the user's active confirmation. Note that this would substantially impact user experience, so this should be used sparingly and only for especially sensitive actions.

Verify the source of the request by validating the `Origin` header if present, or at least the `Referer` header. Discard sensitive requests that originate from a different site.

I Email Address Pattern Found

Cause

Insecure web application programming or configuration

Risk

It is possible to gather sensitive information about the web application such as usernames, passwords, machine name and/or sensitive file locations

Spambots crawl internet sites, set out to find e-mail addresses in order to build mailing lists for sending unsolicited e-mail (spam).

AppScan detected a response containing one or more e-mail addresses, which may be exploited to send spam mail

Furthermore, the e-mail addresses found may be private and thus should not be accessible to the general public.

Fix recommendation

Remove any e-mail addresses from the website so that they won't be exploited by malicious users.

CWE

External references

- [Definition of Spambot \(Wikipedia\)](#)

[Go to Table of Contents](#)

H Integer Overflow

Cause

An Integer Overflow (or wraparound) occurs when a value that is too large is stored (larger than the maximum value the variable can hold) in an integer data type (including byte, short, long, and other types). The most significant bits of the integer are lost, and the remaining value is relative to the minimum value (either 0 or very negative value for signed types).

Risk

When an integer overflow occurs, the interpreted value will appear to have 'wrapped around' past the maximum value and reset back to the minimum value.

The value can unexpectedly become zero or negative. This can have security implications if the value is used to control looping, manage resources (such as memory allocation), or make business logic decisions.

For example, an integer overflow can give money to the customer in addition to their purchases, when the transaction is completed.

In particular, if a mathematical operation results in a number larger than the maximum possible for the integer type, the value wraps around and the variable is set to zero, or negative.

`i=UINT_MAX+1; // Maximum value for a variable of type unsigned int - 4294967295 (0xffffffff). The result is: i=0`

Fix recommendation

Validate all inputs are within an expected range and the sign before relying on their values or using them in arithmetic calculations.

Be sure to check both upper bounds and lower bounds, including negative lower bounds for signed integers (integer overflow is also possible with very large negative numbers).

Use unsigned integers where possible.

Consider using a safe integer-handling library (such as C/C++ `SafeInt` or `IntegerLib`).

Consider enabling compiler extensions that prevent some classes of buffer overflows.

CWE

190

External references

- [SafeInt Library](#)

[Go to Table of Contents](#)

M Login Error Messages Credential Enumeration

Cause

Exceptions and error messages, which may contain sensitive debugging information, are presented to users

Risk

It might be possible to escalate user privileges and gain administrative permissions over the web application

When trying to login using bad credentials, the application generates different error messages when the user inputs an invalid username and an invalid password separately.

By exploiting this behavior, an attacker could experiment through trial and error (the brute force technique) to establish valid usernames for the application, before proceeding to attempt discovery of the associated password.

The result is an enumeration of valid usernames and passwords, which can be used by attackers to access accounts.

Sample Exploit:

If the following requests receive different error messages, it is possible to issue a brute-force attack against the site and enumerate usernames and password:

```
[1] GET /login.asp?username=BAD_USERNAME&password=correct_password
```

```
[2] GET /login.asp?username=correct_username&password=BAD_PASSWORD
```

Fix recommendation

Issue an identical error message to every false login attempt, regardless of which field the error occurred in, especially if either the username or the password fields are wrong.

L Missing "Content-Security-Policy" header

Cause

Insecure web application programming or configuration

Risk

It is possible to gather sensitive information about the web application such as usernames, passwords, machine name and/or sensitive file locations

It is possible to persuade a naive user to supply sensitive information such as username, password, credit card number, social security number etc.

The absence or improper values of CSP can cause the web application being vulnerable to XSS, clickjacking, etc.

The "Content-Security-Policy" header is designed to modify the way browsers render pages, and thus to protect from various cross-site injections, including Cross-Site Scripting. It is important to set the header value correctly, in a way that will not prevent proper operation of the web site. For example, if the header is set to prevent execution of inline JavaScript, the web site must not use inline JavaScript in its pages.

To protect against Cross-Site Scripting, Cross-Frame Scripting and clickjacking, it is important to set the following policies with proper values:

Both of 'default-src' and 'frame-ancestors' policies, *OR* all of 'script-src', 'object-src' and 'frame-ancestors' policies.

For 'default-src', 'script-src' and 'object-src', insecure values such as '*', 'data:', 'unsafe-inline' or 'unsafe-eval' should be avoided.

For 'frame-ancestors', insecure values such as '*' or 'data:' should be avoided.

Additionally for 'script-src', and 'default-src' (fallback directive for 'script-src') 'self' is considered insecure and should be avoided.

Please refer the following links for more information.

Please note that "Content-Security-Policy" includes four different tests. A general test that verifies if the "Content-

Security-Policy" header is being used and three additional tests that check if "Frame-Ancestors", "Object-Src" and "Script-Src" were configured correctly.

Fix recommendation

Configure your server to send the "Content-Security-Policy" header.

It is recommended to configure Content-Security-Policy header with secure values for its directives as below:

For 'default-src', and 'script-src' secure values such as 'none', or <https://any.example.com>.

For 'frame-ancestors', and 'object-src' secure values such as 'self', 'none' or <https://any.example.com> are expected.

"unsafe-inline" and "unsafe-eval" must not be used in any circumstance. Using nonce / hash would be only considered for short-term workaround.

For Apache, see:

http://httpd.apache.org/docs/2.2/mod/mod_headers.html

For IIS, see:

<https://technet.microsoft.com/pl-pl/library/cc753133%28v=ws.10%29.aspx>

For nginx, see:

http://nginx.org/en/docs/http/nginx_http_headers_module.html

I Missing "Referrer policy" Security Header

Cause

Insecure web application programming or configuration

Risk

It is possible to gather sensitive information about the web application such as usernames, passwords, machine name and/or sensitive file locations

It is possible to persuade a naive user to supply sensitive information such as username, password, credit card number, social security number etc.

The absence or improper values of Referrer Policy can cause URL leak itself, and even sensitive information contained in the URL will be leaked to the cross-site.

This is a part of ruleset to check if Referrer Policy is present and if so to test its configuration. The "Referer Policy" header defines what data is made available in the Referer header, and for navigation and iframes in the destination's (document.referrer). This header is designed to modify the way browsers render pages, and thus to prevent cross-domain Referer leakage. It is important to set the header value correctly, in a way that will not prevent proper operation of the web site.

Referer header is a request header that indicates the site which the traffic originated from. If there is no adequate prevention in place, the URL itself, and even sensitive information contained in the URL will be leaked to the cross-site.

"no-referrer-when-downgrade" and "unsafe-url" are the policies which leaks the Full Url for the ThirdParty Sites. The remaining policies are "no-referrer", "origin", "origin-when-cross-origin", "same-origin", "strict-origin", "strict-origin-when-cross-origin".

Please refer the following links for more information.

Fix recommendation

Configure your server to send the "Referrer Policy" header.

It is recommended to configure Referrer Policy header with secure values for its directives as below:

"strict-origin-when-cross-origin" offers more privacy. With this policy, only the origin is sent in the Referer header of cross-origin requests.

For Google Chrome, see:

<https://developers.google.com/web/updates/2020/07/referrer-policy-new-chrome-default>
▪ <https://developers.google.com/web/updates/2020/07/referrer-policy-new-chrome-default>
external

For Firefox , see:

<https://developer.mozilla.org/en-US/docs/Web/HTTP/Headers/Referrer-Policy>.
▪ <https://developer.mozilla.org/en-US/docs/Web/HTTP/Headers/Referrer-Policy>.

L Missing or insecure "frame-ancestors" directive in CSP

Cause

Insecure web application programming or configuration

Risk

The Content-Security-Policy: frame-ancestors 'none' header prevents API-driven web interfaces from being embedded in frames or iframes, effectively protecting against clickjacking attacks.

Without this directive, attackers can load the API's frontend in a hidden frame on a malicious site and trick users into performing unintended actions, such as clicking buttons or submitting forms, potentially leading to data loss or privilege escalation.

This risk is especially severe for APIs that expose sensitive data or privileged operations.

Fix recommendation

To ensure that the API endpoints cannot be embedded in any frame or iframe, set the Content-Security-Policy: frame-ancestors 'none' header on all API endpoint responses.

CWE

1032

[Go to Table of Contents](#)

M Missing or insecure Cross-Origin-Embedder-Policy (COEP) header

Cause

Insecure web application programming or configuration

Risk

Embedding cross-origin resources like scripts or images without restrictions makes your site vulnerable to untrusted code execution and side-channel leaks. An attacker can include opaque third-party resources that don't use proper CORS headers, creating security holes even without direct script execution. This attack vector relies on silently pulling in third-party resources that bypass validation.

Without COEP, attackers can embed untrusted resources that bypass CORS enforcement, opening the door to data leaks and breaking cross-origin isolation required for secure APIs.

Fix recommendation

Set the header "Cross-Origin-Embedder-Policy: require-corp" to enforce that only CORS-enabled or same-origin resources can be loaded.

CWE

200

External references

- [OWASP Secure Headers Project - COEP](#)

[Go to Table of Contents](#)

M Missing or insecure Cross-Origin-Opener-Policy (COOP) header

Cause

Insecure web application programming or configuration

Risk

Modern browsers allow windows and tabs to interact if they open each other, even when from different origins. This behavior can expose your site to cross-origin side-channel attacks, by allowing malicious sites to share a browsing context with yours. The attack vector involves the attacker opening your site in a new tab or iframe, and using shared references like 'window.opener'.

Without COOP, a malicious site can open your page in a new tab and exploit shared browsing context to perform side-channel attacks, potentially leaking cross-origin data like session tokens or sensitive content.

Fix recommendation

Set the header "Cross-Origin-Opener-Policy: same-origin" to ensure your site runs in a separate browsing context group, isolating it from other origins.

CWE

200

External references

- [OWASP Secure Headers Project - COOP](#)

[Go to Table of Contents](#)

M Missing or insecure Cross-Origin-Resource-Policy (CORP) header

Cause

Insecure web application programming or configuration

Risk

Web applications often serve static resources like images, scripts, or APIs that aren't meant to be embedded or reused by other websites. Without protection, a malicious site can embed your resources and extract sensitive data, sometimes using timing attacks or leaking metadata via browser behavior. This happens when resources are not protected and are freely accessible cross-origin.

Without CORP, third-party sites can embed and misuse your private resources, enabling data leaks or piggybacking on authenticated sessions.

Fix recommendation

Set the "Cross-Origin-Resource-Policy" header on resources to "same-origin" or "same-site" to prevent unauthorized embedding or reuse by third parties.

CWE

200

External references

- [OWASP Secure Headers Project - CORP](#)

[Go to Table of Contents](#)

L Permanent Cookie Contains Sensitive Session Information

Cause

The web application stores sensitive session information in a permanent cookie (on disk)

Risk

It may be possible to steal session information (cookies) that was kept on disk as permanent cookies

During the application test, it was detected that sensitive session information such as user credentials or session tokens were stored in a permanent cookie on the client's computer.

[1] Since other users may use the computer, this information may be compromised or used for identity theft or user impersonation.

[2] If the computer will be compromised, the account information may be stolen and used later by a malicious user.

In addition, several privacy regulations require that users will be identified uniquely before accessing sensitive information. Since a permanent cookie may allow other users to logon to the web application without authenticating, this may not comply with several privacy regulations.

Fix recommendation

Make sure that sensitive session information such as user credentials or session tokens will always be stored in non-permanent cookies (RAM cookies) only. This is achieved by avoiding setting the "Expires" field in the cookie. If the "Expires" attribute is missing, the browser will automatically treat it as a session cookie.

L Trusted types in scripts not enforced in CSP

Cause

Insecure web application programming or configuration

Risk

The "Content-Security-Policy" header is designed to modify the way browsers render pages, and thus to protect from various cross-site injections, including Cross-Site Scripting. It is important to set the header value correctly, in a way that will not prevent proper operation of the web site.

Not using Trusted Types can allow attackers to inject scripts, as a result, this increases the risk of XSS vulnerabilities.

Fix recommendation

Consider using 'require-trusted-types-for' directive to prevent DOM-based XSS attacks.

Add "require-trusted-types-for 'script'" directive to your CSP to enforce Trusted Types for scripts.

I Unsanitized user input reflected in JSON

Cause

Cross-site scripting (XSS) vulnerabilities arise when an attacker sends malicious code to the victim's browser, mostly using JavaScript. A vulnerable web application might embed untrusted data in the output, without filtering or encoding it. In this way, an attacker can inject a malicious script to the application, and the script will be returned in the response. This will then run on the victim's browser.

In particular, sanitization of hazardous characters was not performed correctly on user input or untrusted data.

In reflected attacks, an attacker tricks an end user into sending request containing malicious code to a vulnerable Web server, which then reflects the attack back to the end user's browser.

The server receives the malicious data directly from the HTTP request and reflects it back in the HTTP response. The most common method of sending malicious content is adding it as a parameter in a URL that is posted publicly or e-mailed directly to the victim. URLs that contain the malicious script constitute the core of many phishing schemes, whereby the convinced victim visits a URL that refers to a vulnerable site. The site then reflects the malicious content back to the victim, and then the content is executed by the victim's browser.

Risk

XSS attacks can expose the user's session cookie, allowing the attacker to hijack the user's session and gain access to the user's account, which could lead to impersonation of users.

An attacker could modify and view the users' records and perform transactions as those users. The attacker may be able to perform privileged operations on behalf of the user, or gain access to any sensitive data belonging to the user. This would be especially dangerous if the user has administrator permissions.

The attacker could even run a malicious script on the victim's browser which would redirect the user to other pages or sites, modify content presentation, or even make it possible to run malicious software or a crypto miner.

Exploit example

The following example shows a script that returns a parameter value in the response. The parameter value is sent to the script using a GET request, and then returned in the response embedded in the HTML.

```
GET /index.aspx?name=JSmith HTTP/1.1
```

```
HTTP/1.1 200 OK
Server: SomeServer
Date: Sun, 01 Jan 2002 00:31:19 GMT
Content-Type: text/html
Accept-Ranges: bytes
Content-Length: 27

<HTML>
Hello JSmith
</HTML>
```

An attacker might leverage the attack like this. In this case, the JavaScript code will be executed by the browser.

```
GET /index.aspx?name=>"><script>alert('XSS')</script> HTTP/1.1
```

```
HTTP/1.1 200 OK
Server: SomeServer
Date: Sun, 01 Jan 2002 00:31:19 GMT
Content-Type: text/html
Accept-Ranges: bytes
Content-Length: 83

<HTML>
Hello >"><script>alert('XSS')</script>
</HTML>
```

Fix recommendation

Fully encode all dynamic data from an untrusted source that is inserted into the webpage, to ensure it is treated as literal text and not as a script that could be executed or markup that could be rendered.

Consider the context in which your data will be used, and contextually encode the data as close as possible to the actual output: e.g. HTML encoding for HTML content; HTML Attribute encoding for data output to attribute values; JavaScript encoding for dynamically generated JavaScript. For example, when HTML encoding non-alphanumeric characters into HTML entities, `<` and `>` would become `<` and `>`.

As an extra defensive measure, validate all external input on the server, regardless of source. Carefully check each input parameter against a rigorous positive specification (allowlist) defining data type; size; range; format; and acceptable values. Regular expressions or framework controls may be useful in some cases, though this is not a replacement for output encoding.

Output encoding and data validation must be done on all untrusted data, wherever it comes from: e.g. form fields, URL parameters, web service arguments, cookies, any data from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files and filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

For every web page that is returned by the server, explicitly set the `Content-Type` HTTP response header. This header value should define a specific character encoding (charset), such as `ISO-8859-1` or `UTF-8`. When an encoding is not specified, the web browser may choose a different encoding by guessing which encoding is actually being used by the web page, which would allow a potential attacker to bypass XSS protections.

Additionally, set the `httpOnly` flag on the session cookie, to prevent any XSS exploits from stealing a user's cookie.

Prefer using a framework or standard library that prevents this vulnerability by automatically encoding all dynamic output based on context, or at least that provides constructs that make it easier to avoid.

For every web page that is returned by the server, explicitly set the `Content-Security-Policy` HTTP response header, in order to make it significantly more difficult for the attacker to actually exploit the XSS attack.
